

# Models of linear dependent type theory

Martin Lundfall

October 23, 2017

## Abstract

The role that types play in type theory can be seen as a simultaneous generalisation of the concept of a set, proposition and data type. In linear type theory, this view can be extended by interpreting linear types as a particular kind of resource that is *consumed* in the derivation. In this paper, we construct a type theory which deals with non-linear, dependent types (what we will call *cartesian*), and linear types, where both constructs are allowed to depend on terms of cartesian types. In the interplay between the cartesian and linear types we develop two new type formers,  $\Box_{x:A} B$  and  $\sqsubset_{x:A} B$ , akin to  $\Pi$  and  $\Sigma$ , but where the dependent type  $B$  (and therefore the resulting construct) is linear. The !-exponential from linear logic is deconstructed into two modalities,  $M$  and  $L$ , which turns linear types into cartesian types and vice versa. We construct a semantic framework where the type theory is interpreted by constructing a base category of cartesian contexts equipped with two fibrations, whose fibers over a context  $\Gamma$  give rise to the categories of linear and cartesian types in  $\Gamma$ . The operators  $M$  and  $L$  give rise to a fiberwise adjunction between these.

## 2 Introduction

## 3 Preliminaries

The paper is largely split into two sections; syntax and semantics. Familiarity with basic category theoretic concepts like limits, adjoints, monoidal categories is assumed.

### 3.1 Dependent type theory

From a syntactic perspective, a *type* is a syntactic object whose meaning and function stems from the ways in which it interacts with the derivation rules of a particular *type theory*. A definition of this kind is the best we can hope for if we want to view type theory as a foundational system of mathematical reasoning, as it does not rely on any predefined semantic framework. Taking a foundational view, the question to ask is not *what is a type?* but rather, for any other mathematical construction  $X$ , one should ask *how do I express  $X$ , type theoretically?*

Approaching type theory from the perspective of logic, we can form a first approximation of the definition of a type as a generalization of a proposition and a set.

### 3.2 Linear type theory

Linear logic is a substructural logic in which the rules of weakening and contraction:

$$\frac{\Gamma, \Delta \vdash B}{\Gamma, A, \Delta \vdash B} \text{ Weak} \qquad \frac{\Gamma, A, A, \Delta \vdash B}{\Gamma, A, \Delta \vdash B} \text{ Contr}$$

are not admissible.

In other words, assumptions cannot be freely assumed or dismissed; they must be used exactly once in the conclusion. In linear logic, we are inclined to think of a sequent  $A_1, A_2, \dots, A_n \vdash B$  as modelling a function or process in which the assumptions  $A_1, A_2, \dots, A_n$  are *resources used* to yield  $B$ . As a first, toy example, we consider the chemical process of burning hydrogen:

**Example 3.1.** Consider the following primitive derivation rule:

$$O_2 \otimes H_2 \otimes H_2 \vdash H_2O \otimes H_2O$$

stating that given an oxygen molecule and two hydrogen molecules, burning yields two water molecules. If weakening was admissible, we would be able to assume an additional hydrogen molecule without changing the antecedent, which does not make sense under the resource interpretation of linear logic.

Just as intuitionistic logic naturally extends to (dependent) type theory under the slogan of propositions as types, linear logic can be extended to a linear type theory, where sequents are decorated with proof terms:

$$x_1 : A_1, x_2 : A_2, \dots, x_n : A_n \vdash t : B$$

and here linearity implies that the free variables of  $t$  are  $x_1, x_2, \dots, x_n$ , each appearing exactly once.

Semantically, the generalization of a linear logic to linear type theory corresponds to the generalisation of symmetric monoidal preorders to symmetric monoidal categories.

Interest in linear type theory stems from disparate sources. From the perspective of (classical) computer science, it can be used for modelling state and storage, with linear variables denoting resources like pointers or files [10], or even as a theoretical description of the resource handling of a blockchain [14]. In quantum physics, linear types respect the no cloning theorem of quantum states, and are also proposed as a syntax for quantum computation [4]. From a semantic perspective, linear type theory can be interpreted in a symmetric monoidal closed categories, generalising the structure of a cartesian closed categories in which (non-dependent) type theories are interpreted.

### 3.3 Fibrations

A general heuristic for modelling a mathematical object  $E$  dependent over another object  $B$  is to specify a *projection* morphism  $p : E \rightarrow B$  subject to certain constraints. For example, a family of sets  $A_i$  indexed by the set  $I$  might equally well be understood as the set  $E = \bigsqcup_{i \in I} A_i$  together with a morphism  $p : E \rightarrow I$  such that  $p^{-1}(i) = A_i$ . This is the idea guiding the concept of a fibration. Depending on which kind of mathematical object we are dealing with, we impose various conditions on the projection  $p : E \rightarrow B$  to be able to *lift* certain structure of the base  $B$  into *fibers*  $E_b = p^{-1}(b)$  for  $b \in B$ .

### 3.3.1 Grothendieck fibrations

In the context of categories, the appropriate notion is that of a **Grothendieck fibration**, often just called **fibration**. In order for a functor  $p : E \rightarrow B$  to be a fibration, one needs to be able to lift arrows in the base category  $B$  to arrows in  $E$ . We do this by asking for the existence of certain *cartesian arrows* in  $E$ .

**Definition 3.2** (Cartesian arrow). Given a functor  $p : E \rightarrow B$ , an arrow  $f : e' \rightarrow e''$  of  $E$  is said to be **cartesian** with respect to  $p$  if for every  $h : e \rightarrow e''$  and  $\alpha : p(e) \rightarrow p(e')$  such that  $p(f)\alpha = p(h)$ , there is a unique arrow  $\hat{\alpha} : e \rightarrow e'$  such that  $p(\hat{\alpha}) = \alpha$  and  $f\hat{\alpha} = h$ .

The situation is illustrated in the following diagrams:

$$\begin{array}{ccc} p(e) & & e \\ \downarrow \forall \alpha & \searrow p(h) & \downarrow \exists \hat{\alpha} \\ p(e') & \xrightarrow{p(f)} & p(e'') \\ & & \downarrow f \\ & & e'' \end{array}$$

**Definition 3.3** (Grothendieck fibration). A functor  $p : E \rightarrow B$  is a **Grothendieck fibration** if, for every  $e \in E$ ,  $b \in B$  and arrow  $f : b \rightarrow p(e)$  in  $B$ , there exists a cartesian arrow  $f^*$  in  $E$  such that  $p(f^*) = f$ .

We will refer to a cartesian arrow  $f^*$  for which  $p(f^*) = f$  as a **lift** of  $f$ . Although lifts are not uniquely determined, from the condition of cartesianness their domain will be determined up to unique isomorphism. A basic review of Grothendieck fibrations particularly relevant to the semantics of dependent type theory can be found in [8]. We will simply repeat the basic notions that will be used in our investigations.

For any object  $b \in B$  in the base, we call the subcategory of  $E$  which is mapped to  $b$  and its identity morphism the **fiber** over  $b$ . This will be denoted  $E_b$ . A fibration  $p : E \rightarrow B$  induces for every  $u : b \rightarrow b'$  in  $B$  a functor  $u^* : E_{b'} \rightarrow E_b$  by sending every object to the domain of the cartesian arrow associated to  $u^*$ . Such functors will be unique up to unique natural isomorphism. In general, for two compatible morphisms  $u$  and  $v$  in the base, a lift of a composition is not identical to the composition of a lift, only naturally isomorphic. In other words, we have  $u^* \circ v^* \cong (u \circ v)^*$ , but not functoriality on the nose. Fibrations for which there are lifts of morphisms such that the equalities hold on the nose are called **split**.

**Definition 3.4** (Cartesian functor). Let  $p : E \rightarrow B$  and  $q : E' \rightarrow B$  be fibrations over the same base. A functor  $F : E \rightarrow E'$  is **cartesian** if  $qF = p$  and cartesian morphisms in  $E$  with respect to  $p$  are mapped to cartesian morphisms in  $E'$  with respect to  $q$ .

This determines a category **Fib**( $B$ ), consisting of fibrations over  $B$  and cartesian functors between them. More generally, one can construct a category **Fib** whose morphisms from fibrations  $p : E \rightarrow B$  and  $q : E' \rightarrow B'$  are pairs of functors  $(F, G)$  where  $F : E \rightarrow E'$  and  $G : B \rightarrow B'$  such that  $G \circ p = q \circ F$  and  $F$  preserves cartesian morphisms. In fact, the functor **Fib**  $\rightarrow$  **Cat** sending a fibration to its base is itself a fibration whose fibers are **Fib**( $B$ ) for any small category  $B$ .

With the notion of a fibered natural transformation, **Fib** forms a 2-category.

**Definition 3.5** (Fibered natural transformation). For two pairs of parallel functors  $F, H$  and  $G, J$  between fibrations  $(E, B)$  and  $(E', B')$ , as illustrated in the commutative square:

$$\begin{array}{ccc} E & \begin{array}{c} \xrightarrow{F} \\ \xrightarrow{G} \end{array} & E' \\ \downarrow p & & \downarrow p' \\ B & \begin{array}{c} \xrightarrow{H} \\ \xrightarrow{J} \end{array} & B' \end{array}$$

a **Fibered natural transformation**  $(\lambda, \lambda')$  between  $(F, H)$  and  $(G, J)$  is a pair of natural transformations  $\lambda : G \rightarrow F$  and  $\lambda' : A \rightarrow B$  such that  $p'(\lambda) = p_\lambda$ .

Notice that this definition does not ask for  $F$  and  $G$  to be cartesian functors. But when that is the case, fibered natural transformations between the parallel morphisms  $(F, A)$  and  $(G, A)$  in **Fib** are the 2-morphisms of this 2-category.

An important special case of this is when  $B = B'$  and  $H = J = 1_B$ . Then a fibered natural transformation  $\lambda : F \rightarrow G$  is simply a natural transformation such that all of its components are sent to identities via  $p'$ . Such a natural transformation is sometimes called *vertical*.

**Definition 3.6.** Let  $p : E \rightarrow B$  and  $q : D \rightarrow B$  be fibrations over the same base and  $F : E \rightarrow D$  and  $G : D \rightarrow E$  cartesian functors with respect to these.  $F$  is called a **fibered left adjoint** of  $G$  if  $F \dashv G$  in the usual way and the unit  $\eta$  of the adjunction is vertical. Such an adjunction will be called a **fiber adjunction**.

### 3.3.2 Other types of fibrations

In exploring models of linear and dependent types, fibrations of other structures will arise. Two important examples will be fibrations of groupoids and fibrations of monoidal categories.

**Definition 3.7.** A map  $p : G \rightarrow H$  in **Grpd** is a **fibration of groupoids** if for every  $g \in G$  and  $f : p(g) \rightarrow h$  in  $H$ , there exists an object  $g'$  and map  $\hat{f} : g \rightarrow g'$  in  $G$  such that  $p(g') = h$  and  $p(\hat{f}) = f : p(g) \rightarrow p(g')$ .

When considering fibrations of monoidal categories, we distinguish between the case where both the fibration and the base are monoidal categories, and when we simply want each fiber to be a monoidal category and the induced functors between these to be monoidal functors. The former notion is that of a monoidal fibration:

**Definition 3.8.** A **monoidal fibration** is a functor  $\Phi : E \rightarrow B$  such that

- $\Phi$  is a Grothendieck fibration
- $E$  and  $B$  are monoidal categories and  $\Phi$  is a strict monoidal functor, and
- the tensor product of  $E$  preserves cartesian arrows.

In particular, when  $B$  is a cartesian monoidal category, an arrow  $f : b \rightarrow p(e)$  induces a strong monoidal functor  $f^* : B_e \rightarrow B_{f^*e}$  between the fibers [16].

The more general structure of a lax monoidal fibration [18], does not require neither  $E$  nor  $B$  to be monoidal. We simply want each fiber of  $E$  to carry a monoidal structure, and that the induced functors between fibers are monoidal.

**Definition 3.9.** A **lax monoidal fibration** is a fibration  $p : E \rightarrow B$  along with

1. Two functors  $\otimes : E \times_B E \rightarrow E$  and  $I : B \rightarrow E$  fitting into the following diagram:

$$\begin{array}{ccccc} E \times_B E & \xrightarrow{\otimes} & E & \xleftarrow{I} & B \\ & \searrow & \downarrow p & \swarrow 1_B & \\ & & B & & \end{array}$$

2. Three fibered natural isomorphisms  $\alpha, \lambda$  and  $\rho$  associated with the diagrams:

$$\begin{array}{ccc} E \times_B E \times_B E & \xrightarrow{1_E \times_B \otimes} & E \times_B E \\ \downarrow \otimes \times_B 1_E & \nearrow \alpha & \downarrow \otimes \\ E \times_B E & \xrightarrow{\otimes} & E \end{array}$$

and

$$\begin{array}{ccccc} B \times_B E & \xrightarrow{I \times_B 1_E} & E \times_B E & \xleftarrow{1_E \times I} & E \times_B B \\ & \searrow \pi_2 & \downarrow \otimes & \swarrow \pi_1 & \\ & & E & & \end{array}$$

$\lambda : \pi_2 \Rightarrow \otimes \leftarrow \pi_1$

3. such that  $\alpha, \lambda$  and  $\rho$  satisfies the pentagon and triangle identities in each fiber.

4. for every  $b \in B$ ,  $\rho_{I_b} = \lambda_{I_b}^{-1} : I_b \otimes I_b \rightarrow I_b$

These conditions are sufficient for each fiber to be a monoidal category and for the induced functors between fibers to be (lax) monoidal [18].

**Example 3.10.** An example of a fibration that is lax monoidal but not monoidal is the fibration **Gph**  $\rightarrow$  **Set** taking a directed graph defined by  $(V, E, \text{dom}, \text{cod} : E \rightarrow V)$  to its underlying set of vertices,  $V$ . For two graphs  $\mathcal{A} = (A, O, \text{dom}_A, \text{cod}_A)$  and  $\mathcal{B} = (B, O, \text{dom}_B, \text{cod}_B)$  over the same fiber **Gph** <sub>$O$</sub> , we define their tensor product by:

$$\mathcal{A} \otimes \mathcal{B} = (A \times_O B, \text{cod}_A \circ \pi_1, \text{dom}_B \circ \pi_2)$$

where  $A \times_O B$  is the pullback in the following diagram:

$$\begin{array}{ccc} A \times_O B & \xrightarrow{\pi_2} & B \\ \downarrow \pi_1 & & \downarrow \text{cod}_B \\ A & \xrightarrow{\text{dom}_A} & O \end{array}$$

This tensor product is only defined over graphs with the same underlying set, i.e. living in the same fiber.

### 3.4 Enriched and higher categories

The concept of a category can be generalized in a few different directions. In exploring semantics of linear type theory, our first encounter with such structures will be enriched categories, where hom-sets are generalized to “hom-objects” of a monoidal category  $\mathcal{V}$ .

**Definition 3.11.** Recall that a functor  $F : \mathcal{C} \rightarrow \mathcal{D}$  is **monoidal** if there exists a natural transformation  $\mu : F \times F \rightarrow F$  with components  $\mu_{A,B} : F(A) \otimes_{\mathcal{D}} F(B) \rightarrow F(A \otimes_{\mathcal{C}} B)$  and a morphism  $I_{\mathcal{D}} \rightarrow F(I_{\mathcal{C}})$ . Satisfying the following naturality conditions:

1. **(Associativity)** For all objects  $x, y, z \in \mathcal{C}$  the following diagram commutes:

$$\begin{array}{ccc}
 (F(x) \otimes_{\mathcal{D}} F(y)) \otimes_{\mathcal{D}} F(z) & \xrightarrow{a_{F(x), F(y), F(z)}^{\mathcal{D}}} & F(x) \otimes_{\mathcal{D}} (F(y) \otimes_{\mathcal{D}} F(z)) \\
 \downarrow \mu_{x,y} \otimes id & & \downarrow id \otimes \mu_{y,z} \\
 F(x \otimes_{\mathcal{C}} y) \otimes_{\mathcal{D}} F(z) & & F(x) \otimes_{\mathcal{D}} (F(y \otimes_{\mathcal{C}} z)) \\
 \downarrow \mu_{x \otimes_{\mathcal{C}} y, z} & & \downarrow \mu_{x, y \otimes_{\mathcal{C}} z} \\
 F((x \otimes_{\mathcal{C}} y) \otimes_{\mathcal{C}} z) & \xrightarrow{F(a_{x,y,z}^{\mathcal{C}})} & F(x \otimes_{\mathcal{C}} (y \otimes_{\mathcal{C}} z))
 \end{array}$$

where  $a^{\mathcal{C}}$  and  $a^{\mathcal{D}}$  denote the associators of the monoidal categories;

2. **(Unitality)** For all  $x \in \mathcal{C}$  the following diagrams commutes:

$$\begin{array}{ccc}
 1_{\mathcal{D}} \otimes_{\mathcal{D}} F(x) & \xrightarrow{\epsilon \otimes id} & F(1_{\mathcal{C}}) \otimes_{\mathcal{D}} F(x) \\
 \downarrow \ell_{F(x)}^{\mathcal{D}} & & \downarrow \mu_{1_{\mathcal{C}}, x} \\
 F(x) & \xleftarrow{F(\ell_x^{\mathcal{C}})} & F(1 \otimes_{\mathcal{C}} x)
 \end{array}$$

and

$$\begin{array}{ccc}
 F(x) \otimes_{\mathcal{D}} 1_{\mathcal{D}} & \xrightarrow{id \otimes \epsilon} & F(x) \otimes_{\mathcal{D}} F(1_{\mathcal{C}}) \\
 \downarrow r_{F(x)}^{\mathcal{D}} & & \downarrow \mu_{x, 1_{\mathcal{C}}} \\
 F(x) & \xleftarrow{F(r_x^{\mathcal{C}})} & F(x \otimes_{\mathcal{C}} 1)
 \end{array}$$

where  $\ell^{\mathcal{C}}, \ell^{\mathcal{D}}, r^{\mathcal{C}}, r^{\mathcal{D}}$  denote the left and right unitors of the two monoidal categories, respectively.

**Definition 3.12.** For a monoidal category  $\mathcal{V}$ , a  $\mathcal{V}$ -**enriched category**  $\mathcal{C}$ , consists of the following:

1. A set  $\mathcal{C}_0$  of objects,
2. for each pair  $a, b \in \mathcal{C}_0$ , an object  $V_{a,b} \in \mathcal{V}$ ,
3. for every  $a, b, c \in \mathcal{C}_0$ , a *composition law*, i.e. a functor  $M_{a,b,c} : V_{b,c} \otimes V_{a,b} \rightarrow V_{a,c}$  and
4. an identity element  $j_a : I \rightarrow V_{a,a}$

such that for all  $a, b, c, d$ , the following associativity and identity diagrams commute:

$$\begin{array}{ccc}
 (V_{c,d} \otimes V_{b,c}) \otimes V_{a,b} & \xrightarrow{\alpha} & V_{c,d} \otimes (V_{b,c} \otimes V_{a,b}) \\
 \downarrow M_{b,c,d} \otimes 1_{V_{a,b}} & & \downarrow 1_{V_{c,d}} \otimes M_{a,b,c} \\
 V_{b,d} \otimes V_{a,b} & & V_{c,d} \otimes V_{a,c} \\
 \searrow M_{a,b,d} & & \swarrow M_{a,c,d} \\
 & V_{a,d} & \\
 \\ 
 I \otimes V_{a,b} & \xrightarrow{l} & V_{a,b} \xleftarrow{r} V_{a,b} \otimes I \\
 \downarrow j_b \otimes 1_{V_{a,b}} & \nearrow M_{a,b,b} & \nwarrow M_{a,a,b} \downarrow 1_{V_{a,b}} \otimes j_a \\
 V_{b,b} \otimes V_{a,b} & & V_{a,b} \otimes V_{a,a}
 \end{array}$$

where  $\alpha, l$  and  $r$  are the associator, and left and right unitor isomorphisms associated with the monoidal structure of  $\mathcal{V}$ .

Note that for the special case of  $\mathcal{V} = \mathbf{Set}$  we get back the definition of a category. Plenty of examples of constructions in enriched categories can be found in the comprehensive introduction *Basic concepts of enriched category theory* by Max Kelly, [9].

Another generalization of a category is suggested by the direction in which categories generalize sets/classes by allowing arrows between objects. Thinking of arrows as one-dimensional objects between zero-dimensional objects, one can imagine the existence of 2-dimensional arrows between 1-dimensional ones. This leads to the notion of a 2-category. These come in two different forms, strict 2-categories (or just 2-categories) or weak 2-categories (also known as bicategories). Equipped with the notion of an enriched category, strict 2-categories can be defined concisely as:

**Definition 3.13.** A (strict) **2-category** is a  $\mathbf{Cat}$ -enriched category.

Breaking down this definition provides a more illuminating view. A strict 2-category,  $\mathcal{C}$ , consists of

- a collection of objects  $\mathcal{C}_0$ ,
- for any pair of objects  $a, b \in \mathcal{C}_0$ , a category  $\mathcal{C}_{a,b}$ , whose objects will be called “1-morphisms” and whose morphisms are renamed “2-morphisms”.
- for any object  $a \in \mathcal{C}_0$ , an “identity” functor  $1_a : \mathbf{1} \rightarrow \mathcal{C}_{a,a}$ ,
- for any triple of objects  $a, b, c \in \mathcal{C}_0$ , a functor  $Comp : \mathcal{C}_{b,c} \times \mathcal{C}_{a,b} \rightarrow \mathcal{C}_{a,c}$  satisfying the associativity and identity diagrams from the definition of enriched categories.

The action of  $Comp$  on 1-morphisms is called “horizontal composition” and is written  $gf := Comp(g, f)$  for  $f \in \mathcal{C}_{a,b}$  and  $g \in \mathcal{C}_{b,c}$ , whereas the composition between 2-morphisms  $\alpha : f \Rightarrow g$ ,  $\alpha' : g \Rightarrow h$  for  $f, g, h \in \mathcal{C}_{a,b}$  is written  $\alpha' \circ \alpha$ . Thanks to the functoriality of  $Comp$ , these satisfy the following *interchange law*:

$$(\beta' \circ \beta)(\alpha' \circ \alpha) = (\beta' \alpha') \circ (\beta \alpha)$$

The path from strict 2-categories to weak 2-categories is marched to the category theoretic slogan that it is undesirable to speak of equality between objects in a category. 2-morphisms give us a way of relating 1-morphisms up to isomorphism instead of on-the-nose equality. Thus we are inclined to loosen the restriction of the associativity and unital diagrams in the definition of a 2-category to only commute up to coherent natural isomorphism:

**Definition 3.14.** A **weak 2-category**  $\mathcal{C}$  is a collection of objects, 1-morphisms and 2-morphisms with composition and identity functors as before, such that for all  $a, b, c, d \in \mathcal{C}_0$ , there exists natural isomorphisms

$$\begin{aligned} \gamma : M_{a,b,d} \circ (M_{b,c,d} \otimes 1_{V_{a,b}}) &\Rightarrow M_{a,c,d} \circ (1_{V_{c,d}} \otimes M_{a,b,c}) \circ a \\ \lambda : l &\Rightarrow M_{a,b,b} \circ (j_b \circ 1_{V_{a,b}}) \\ \rho : r &\Rightarrow M_{a,a,b} \circ (1_{V_{a,b}} \circ j_a) \end{aligned}$$

in other words, associated with the diagrams:

$$\begin{array}{ccc} (V_{c,d} \otimes V_{b,c}) \otimes V_{a,b} & \xrightarrow{\alpha} & V_{c,d} \otimes (V_{b,c} \otimes V_{a,b}) \\ \downarrow M_{b,c,d} \otimes 1_{V_{a,b}} & & \downarrow 1_{V_{c,d}} \otimes M_{a,b,c} \\ V_{b,d} \otimes V_{a,b} & \xrightarrow{\gamma} & V_{c,d} \otimes V_{a,c} \\ \searrow M_{a,b,d} & & \swarrow M_{a,c,d} \\ & V_{a,d} & \end{array}$$
  

$$\begin{array}{ccccc} I \otimes V_{a,b} & \xrightarrow{l} & V_{a,b} & \xleftarrow{r} & V_{a,b} \otimes I \\ \downarrow j_b \otimes 1_{V_{a,b}} & \Downarrow \lambda & \uparrow M_{a,b,b} & \Downarrow \rho & \downarrow 1_{V_{a,b}} \otimes j_a \\ V_{b,b} \otimes V_{a,b} & & & & V_{a,b} \otimes V_{a,a} \end{array}$$

subject to the following coherence conditions:

### 3.5 Monoidal structure of the category of symmetric monoidal categories

In section 6.3, we will consider the category of small symmetric monoidal categories, which is itself a monoidal category. That is, for two symmetric monoidal categories  $\mathcal{A}$  and  $\mathcal{B}$ , there is a symmetric category  $\mathcal{A} \otimes \mathcal{B}$ . We will briefly outline the idea behind the construction of this category and its monoidal structure. The full details, as well as many other results about the monoidal structure of  $\mathbf{SMCat}$ , can be found in [15].

**Definition 3.15.** For  $\mathcal{A}, \mathcal{B} \in \mathbf{SMCat}$ , let their **tensor product category** be the symmetric monoidal category  $\mathcal{A} \otimes \mathcal{B}$  whose objects are the words generated by the constant unit symbol  $I$  and the 2-ary symbol  $\otimes$  and the language of  $Ob(\mathcal{A}) \times Ob(\mathcal{B})$ . In other words,  $Ob(\mathcal{A} \otimes \mathcal{B})$  is generated inductively from:

- $I \in Ob(\mathcal{A} \otimes \mathcal{B})$ , and for  $a \in \mathcal{A}$  and  $b \in \mathcal{B}$ ,  $a \otimes b \in \mathcal{A} \otimes \mathcal{B}$
- If  $X$  and  $Y$  are in  $\mathcal{A} \otimes \mathcal{B}$ , then  $X \otimes Y \in \mathcal{A} \otimes \mathcal{B}$ .

The arrows of  $\mathcal{A} \otimes \mathcal{B}$  are generated by the following:

- A natural isomorphism of associativity, with components  $ass_{X,Y,Z} : (X \otimes Y) \otimes Z \rightarrow X \otimes (Y \otimes Z)$ .
- Natural isomorphism  $l$  and  $r$ , with components  $l_X : X \rightarrow I \otimes X$  and  $r_X : X \rightarrow X \otimes I$ .
- Natural isomorphism  $s$ , with components  $s_{X,Y} : X \otimes Y \rightarrow X \otimes Y$ , satisfying  $s_{X,Y} \circ s_{Y,X} = 1_{Y,X}$ .
- For each  $b \in \mathcal{B}$ , a morphism  $\alpha_b : I \rightarrow I_{\mathcal{A}} \otimes b$ , natural in  $b$ .
- For each  $a \in \mathcal{A}$ , a morphism  $\beta_a : I \rightarrow a \otimes I_{\mathcal{B}}$ , natural in  $a$ .
- For any  $f : b \rightarrow b'$  in  $\mathcal{B}$ , an arrow  $a \otimes f : a \otimes b \rightarrow a \otimes b'$
- For any  $f : a \rightarrow a'$  in  $\mathcal{A}$ , an arrow  $f \otimes a : a \otimes b \rightarrow a' \otimes b$
- For  $X$  and  $f : Y \rightarrow Z$ , an arrow  $X \otimes f : X \otimes Y \rightarrow X \otimes Z$ .

subject to a variety of coherence conditions, outlined in [15].

To provide some intuition for this construction, compare it to the construction of the tensor product of abelian groups. The natural transformation  $\gamma$ , is essentially a categorification of the relation:

$$\begin{aligned} (a_1, b) + (a_2, b) &\sim (a_1 + a_2, b) \\ (a, b_1) + (a, b_2) &\sim (a, b_1 + b_2) \end{aligned}$$

in the presentation of the abelian tensor product as a quotient of the direct product of groups.

The tensor product of symmetric monoidal categories extends to a 2-functor  $Ten : \mathbf{SMCat} \times \mathbf{SMCat} \rightarrow \mathbf{SMCat}$ .

**Definition 3.16.** There is a symmetric monoidal category  $I$ , consisting of words generated by one letter,  $\star$ , where the tensor product is given by word concatenation and the empty word is the unit.

There is a small caveat due to the higher dimensional nature of this construction; the functor  $Ten$  and  $I$  do not technically form a monoidal structure on  $\mathbf{SMCat}$ . The associativity, left and right unitor and symmetries are all functors,  $A : (\mathcal{A} \otimes \mathcal{B}) \otimes \mathcal{C} \rightarrow \mathcal{A} \otimes (\mathcal{B} \otimes \mathcal{C})$  equipped with a corresponding functor,  $A' : (\mathcal{B} \otimes \mathcal{C}) \rightarrow (\mathcal{A} \otimes \mathcal{B}) \otimes \mathcal{C}$ , but  $A \circ A'$  is strictly the identity functor, only up naturally isomorphic to it. One might call this a lax symmetric monoidal 2-categorical structure on  $\mathbf{SMCat}$ .

However, by identifying 1-cells connected by a 2-cell, we get the quotient category  $\mathbf{SMCat}/$ , which has a symmetric closed monoidal structure.

As a final note, which will become important in section 6.3, one can easily see from the definition that if  $\mathcal{A}$  and  $\mathcal{B}$  are groupoids, their tensor product category will be a groupoid as well.

## 4 Syntax

The particular linear dependent type theory under consideration is inspired by the work of Krishnaswami in [10] and Vákár in [17]. Types are either *cartesian*, in which case we simply write  $\Gamma \vdash A$  type, or *linear*, written  $\Gamma \vdash A$  linear. When making typing judgements of linear terms, contexts will be split into two parts, separated by a semicolon. The first part contains *cartesian* assumptions, for which weakening and contraction is allowed, while the second part is the *linear* part, containing ephemeral assumptions that we are also inclined to think of as resources. The derivation rules for linear types will force the linear variables to occur exactly once in the conclusion. Dependent types are restricted to only depend on terms of cartesian types.

### 4.1 Structural rules

We will be dealing with the following judgements:

The basic structural rules for the linear dependent type theory are given in Figure 2. Omitted are the rules concerning judgemental equality, which specify that it is an equality relation which is congruent with respect to the other structural rules.

<b>Judgement:</b>	<b>Meaning:</b>
$\vdash \Gamma \text{ ctxt}$	$\Gamma$ is a well-formed cartesian context.
$\vdash \Gamma; \Xi \text{ ctxt}$	$\Gamma; \Xi$ is a well-formed mixed context
$\Gamma \vdash A \text{ type}$	$A$ is a cartesian type in $\Gamma$
$\Gamma \vdash A \text{ linear}$	$A$ is a linear type in $\Gamma$
$\Gamma \vdash M : A$	$M$ is a term of the cartesian type $A$ in $\Gamma$
$\Gamma; \Xi \vdash M : A$	$M$ is a (linear) term of the linear type $A$ in $\Gamma; \Xi$
$\Gamma \vdash A \equiv A' \text{ type}$	$A$ and $A'$ are equal cartesian types in $\Gamma$
$\Gamma \vdash A \equiv A' \text{ linear}$	$A$ and $A'$ are equal linear types in $\Gamma; \Xi$
$\Gamma \vdash M \equiv N : A$	$M$ and $N$ are equal cartesian terms of $A$ in $\Gamma$
$\Gamma; \Xi \vdash x \equiv y : A$	$x$ and $y$ are equal linear terms of $A$ in $\Gamma; \Xi$

Figure 1: Judgements of linear dependent type theory

$\frac{}{\vdash \cdot \text{ ctxt}} \quad \text{CI-Base}$	$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, \Gamma'; \Xi \vdash t : A'}{\Gamma, x : A, \Gamma'; \Xi \vdash t : A'} \quad \text{Weak-L}$
$\frac{}{\vdash \cdot; \cdot \text{ ctxt}} \quad \text{CM-Base}$	$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, \Gamma' \vdash \mathcal{J}}{\Gamma, x : A, \Gamma' \vdash \mathcal{J}} \quad \text{Weak-I}$
$\frac{\Gamma \vdash A \text{ type}}{\vdash \Gamma, x : A \text{ ctxt}} \quad \text{C-int-ext}$	$\frac{\Gamma \vdash M : A \quad \Gamma, x : A, \Gamma' \vdash \mathcal{J}}{\Gamma, \Gamma'[M/x] \vdash \mathcal{J}[M/x]} \quad \text{Int-subst-1}$
$\frac{\Gamma \vdash A \text{ type} \quad \vdash \Gamma, \Delta \text{ ctxt}}{\vdash \Gamma, x : A, \Delta \text{ ctxt}} \quad \text{C-weak-1}$	$\frac{\Gamma \vdash M : A \quad \Gamma, x : A, \Gamma'; \Xi \vdash t : A'}{\Gamma, \Gamma'[M/x]; \Xi[M/x] \vdash t : A'[M/x]} \quad \text{Int-subst-2}$
$\frac{\Gamma \vdash A \text{ type} \quad \vdash \Gamma, \Delta; \Xi \text{ ctxt}}{\vdash \Gamma, x : A, \Delta; \Xi \text{ ctxt}} \quad \text{C-weak-2}$	$\frac{\Gamma; \Xi, x : A \vdash t : B \quad \Gamma; \Xi' \vdash M : A}{\Gamma; \Xi, \Xi' \vdash t[M/x] : B} \quad \text{Lin-subst}$
$\frac{\vdash \Gamma; \Xi \text{ ctxt} \quad \Gamma \vdash A \text{ linear}}{\vdash \Gamma; \Xi, x : A \text{ ctxt}} \quad \text{C-lin-ext}$	$\frac{\Gamma, x : A, \Gamma' \text{ ctxt}}{\Gamma, x : A, \Gamma' \vdash x : A} \quad \text{Int-var}$
$\frac{\Gamma; \Xi, x : A, y : B, \Xi' \vdash t : A'}{\Gamma; \Xi, y : B, x : A, \Xi' \vdash t : A'} \quad \text{Lin-exch}$	$\frac{\vdash \Gamma; x : A \text{ ctxt}}{\Gamma; x : A \vdash x : A} \quad \text{Lin-var}$

Figure 2: Structural rules

$\mathcal{J}$  denotes a judgement of the form  $A \text{ type}$ ,  $A \text{ linear}$  or  $M : A$  (for a cartesian type  $A$ ).

## 4.2 Cartesian typing rules

The cartesian types that we will use are the standard  $\Pi$ ,  $\Sigma$  and  $Id$ -types. For  $\Sigma$  and  $Id$  we will introduce an extra elimination and computational rule for the case where the type being eliminated into is linear.

$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, x : A \vdash B \text{ type}}{\Gamma \vdash \Pi_{x:A} B \text{ type}} \quad \Pi\text{-F}$	$\frac{\Gamma \vdash M : A \quad \Gamma \vdash N : B[M/x]}{\Gamma \vdash (M, N) : \Sigma_{x:A} B} \quad \Sigma\text{-I}$
$\frac{\Gamma, x : A \vdash b : B}{\Gamma \vdash \lambda x. b : \Pi_{x:A} B} \quad \Pi\text{-I}$	$\frac{\Gamma, t : \Sigma_{x:A} B \vdash C \text{ type} \quad \Gamma, x : A, y : B \vdash c : C[(x, y)/t] \quad \Gamma \vdash s : \Sigma_{x:A} B}{\Gamma \vdash \hat{c}[s] : C[s/t]} \quad \Sigma\text{-E}_1$
$\frac{\Gamma \vdash t : \Pi_{x:A} B \text{ type} \quad \Gamma \vdash M : A}{\Gamma \vdash t(M) : B[M/x]} \quad \Pi\text{-E}$	$\frac{\Gamma, t : \Sigma_{x:A} B \vdash C \text{ linear} \quad \Gamma, x : A, y : B; \Xi \vdash c : C[(x, y)/t] \quad \Gamma \vdash s : \Sigma_{x:A} B}{\Gamma; \Xi[pr_1(s)/x][pr_2(s)/y] \vdash \hat{c}[s] : C[s/t]} \quad \Sigma\text{-E}_2$
$\frac{\Gamma, x : A \vdash b : B \quad \Gamma \vdash M : A}{\Gamma \vdash \lambda x. b(M) \equiv b[M/x] : B[M/x]} \quad \Pi\text{-C}$	$\frac{\Gamma \vdash \hat{c}[(a, b)] : C[(a, b)/t]}{\Gamma \vdash \hat{c}[(a, b)] \equiv c[(a, b)/t] : C[(a, b)/t]} \quad \Sigma\text{-C}_1$
$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, x : A \vdash B \text{ type}}{\Gamma \vdash \Sigma_{x:A} B \text{ type}} \quad \Sigma\text{-F}$	$\frac{\Gamma; \Xi \vdash \hat{c}[(a, b)] : C[(a, b)/t]}{\Gamma; \Xi \vdash \hat{c}[(a, b)] \equiv c[(a, b)/t] : C[(a, b)/t]} \quad \Sigma\text{-C}_2$
$\frac{\vdash \Gamma \text{ ctxt}}{\Gamma \vdash 1 \text{ type}} \quad 1\text{-F}$	$\frac{\Gamma \vdash \hat{c}[\star] : C[\star/x]}{\Gamma \vdash \hat{c}[\star] \equiv c[\star/x] : C[\star/x]} \quad 1\text{-C}$
$\frac{\Gamma \text{ ctxt}}{\Gamma \vdash \star : 1} \quad 1\text{-I}$	
$\frac{\Gamma, x : 1 \vdash C \text{ type} \quad \Gamma \vdash c : C[\star/x] \quad \Gamma \vdash M : 1}{\Gamma \vdash \hat{c}[M] : C[M/x]} \quad 1\text{-E}$	

Figure 3: (Cartesian) dependent sum and product types

$\frac{\Gamma \vdash M : A \quad \Gamma \vdash N : A}{\Gamma \vdash M =_A N \text{ type}} \quad =\text{-F}$	
$\frac{\Gamma \vdash M : A}{\Gamma \vdash \text{refl}(M) : M =_A M} \quad =\text{-I}$	$\frac{\vdash \Gamma, x, y : A, p : x =_A y; \Xi \text{ ctxt} \quad \Gamma, x, y : A, p : x =_A y \vdash C \text{ linear} \quad \Gamma, z : A; \Xi[z/x, z/y, \text{refl}(z)/p] \vdash c : C[z/x, z/y, \text{refl}(z)/p] \quad \Gamma \vdash M : A \quad \Gamma \vdash N : A \quad \Gamma \vdash P : M =_A N}{\Gamma; \Xi[M/x, N/y, P/p] \vdash R_{[x,y,p]}^{\text{Id}}(c, M, N, P) : C[M/x, N/y, P/p]} \quad =\text{-E}_2$
$\frac{\Gamma, x, y : A, p : x =_A y \vdash C \text{ type} \quad \Gamma, z : A \vdash c : C[z/x, z/y, \text{refl}(z)/p] \quad \Gamma \vdash M : A \quad \Gamma \vdash N : A \quad \Gamma \vdash P : M =_A N}{\Gamma \vdash R_{[x,y,p]}^{\text{Id}}(c, M, N, P) : C[M/x, N/y, P/p]} \quad =\text{-E}_1$	$\frac{\Gamma \vdash R_{[x,y,p]}^{\text{Id}}(c, M, M, \text{refl}(M)) : C[M/x, M/y, \text{refl}(M)/p]}{\Gamma; \Xi[M/x, M/y, \text{refl}(M)/p] \vdash R_{[x,y,p]}^{\text{Id}}(c, M, M, \text{refl}(M)) \equiv c[M/z] : C[M/x, M/y, \text{refl}(M)/p]} \quad =\text{-C}_1$
$\frac{\Gamma; \Xi[M/x, M/y, \text{refl}(M)/p] \vdash R_{[x,y,p]}^{\text{Id}}(c, M, M, \text{refl}(M)) \equiv c[M/z] : C[M/x, M/y, \text{refl}(M)/p]}{\Gamma; \Xi[M/x, M/y, \text{refl}(M)/p] \vdash R_{[x,y,p]}^{\text{Id}}(c, M, M, \text{refl}(M)) \equiv c[M/z] : C[M/x, M/y, \text{refl}(M)/p]} \quad =\text{-C}_2$	

Figure 4: (Cartesian) identity type

### 4.3 Linear typing rules

Perhaps the most important linear types are the  $\otimes$ - and  $I$ -types, as they will provide an interpretation of linear contexts. Semantically, we will not distinguish between the context  $\Xi \equiv x_1 : A_1, x_2 : A_2, \dots, x_n : A_n$  and  $x_1 \otimes x_2 \otimes \dots \otimes x_n :$

$$A_1 \otimes A_2 \otimes \dots A_n.$$

$\frac{\Gamma \vdash A \text{ linear} \quad \Gamma \vdash B \text{ linear}}{\Gamma \vdash A \otimes B \text{ linear}} \quad \otimes\text{-F}$	$\frac{}{\Gamma \vdash I \text{ linear}} \quad \text{I-F}$
$\frac{\Gamma; \Xi \vdash a : A \quad \Gamma; \Xi' \vdash b : B}{\Gamma; \Xi, \Xi' \vdash (a, b) : A \otimes B} \quad \otimes\text{-I}$	$\frac{}{\Gamma; \cdot \vdash * : I} \quad \text{I-I}$
$\frac{\Gamma; \Xi' \vdash t : A \otimes B \quad \Gamma; \Xi, x : A, y : B \vdash c : C}{\Gamma; \Xi, \Xi' \vdash \text{let } x, y \text{ be } t \text{ in } c : C} \quad \otimes\text{-E}$	$\frac{\Gamma; \Xi \vdash c : C \quad \Gamma; \Xi' \vdash t : I}{\Gamma; \Xi, \Xi' \vdash \text{let } t \text{ be } * \text{ in } c : C} \quad \text{I-E}$
$\frac{\Gamma; \Xi \vdash \text{let } x, y \text{ be } (a, b) \text{ in } c : C}{\Gamma; \Xi \vdash \text{let } x, y \text{ be } (a, b) \text{ in } c \equiv c[a/x][b/y] : C} \quad \otimes\text{-C}$	$\frac{\Gamma; \Xi \vdash \text{let } * \text{ be } * \text{ in } c : C}{\Gamma; \Xi \vdash \text{let } * \text{ be } * \text{ in } c \equiv c : C} \quad \text{I-C}$

Figure 5: Linear  $\otimes$  and  $I$  type formers

The typing rules for the remaining linear rules are standard.

$\frac{\Gamma \vdash A \text{ linear} \quad \Gamma \vdash B \text{ linear}}{\Gamma \vdash A \multimap B \text{ linear}} \quad \multimap\text{-F}$	$\frac{\Gamma \vdash A \text{ linear} \quad \Gamma \vdash B \text{ linear}}{\Gamma \vdash A \oplus B \text{ linear}} \quad \oplus\text{-F}$
$\frac{\Gamma; \Xi, x : A \vdash b : B}{\Gamma; \Xi \vdash \lambda x. b : A \multimap B} \quad \multimap\text{-I}$	$\frac{\Gamma; \Xi \vdash a : A}{\Gamma; \Xi \vdash \text{inl}(a) : A \oplus B} \quad \oplus\text{-I}_1$
$\frac{\Gamma; \Xi \vdash f : A \multimap B \quad \Gamma; \Xi' \vdash a : A}{\Gamma; \Xi, \Xi' \vdash f(a) : B} \quad \multimap\text{-E}$	$\frac{\Gamma; \Xi \vdash b : B}{\Gamma; \Xi \vdash \text{inr}(b) : A \oplus B} \quad \oplus\text{-I}_2$
$\frac{\Gamma; \Xi \vdash \lambda x. b(a) : B}{\Gamma; \Xi \vdash \lambda x. b(a) \equiv b[a/x] : B} \quad \multimap\text{-C}$	$\frac{\Gamma; \Xi, x : A \vdash c : C \quad \Gamma; \Xi, y : B \vdash d : C; \Gamma; \Xi' \vdash t : A \oplus B}{\Gamma; \Xi, \Xi' \vdash \text{case } t \text{ of } \text{inl}(x) \rightarrow c \parallel \text{inr}(y) \rightarrow d : C} \quad \oplus\text{-E}$
$\frac{\Gamma \vdash A \text{ linear} \quad \Gamma \vdash B \text{ linear}}{\Gamma \vdash A \& B \text{ linear}} \quad \&\text{-F}$	$\frac{\Gamma; \Xi \vdash \text{case } \text{inl}(a) \text{ of } \text{inl}(x) \rightarrow c \parallel \text{inr}(y) \rightarrow d : C}{\Gamma; \Xi \vdash \text{case } \text{inl}(a) \text{ of } \text{inl}(x) \rightarrow c \parallel \text{inr}(y) \rightarrow d \equiv c[a/x] : C} \quad \oplus\text{-C}_1$
$\frac{\Gamma; \Xi \vdash a : A \quad \Gamma; \Xi \vdash b : B}{\Gamma; \Xi \vdash \langle a, b \rangle : A \& B} \quad \&\text{-I}$	$\frac{\Gamma; \Xi \vdash \text{case } \text{inr}(b) \text{ of } \text{inl}(x) \rightarrow c \parallel \text{inr}(y) \rightarrow d : C}{\Gamma; \Xi \vdash \text{case } \text{inr}(b) \text{ of } \text{inl}(x) \rightarrow c \parallel \text{inr}(y) \rightarrow d \equiv d[b/y] : C} \quad \oplus\text{-C}_2$
$\frac{\Gamma; \Xi \vdash t : A \& B}{\Gamma; \Xi \vdash \text{fst}(t) : A} \quad \&\text{-E}_1$	$\frac{}{\Gamma \vdash \top \text{ linear}} \quad \top\text{-F}$
$\frac{\Gamma; \Xi \vdash t : A \& B}{\Gamma; \Xi \vdash \text{snd}(t) : B} \quad \&\text{-E}_2$	$\frac{\vdash \Gamma; \Xi \text{ctxt}}{\Gamma; \Xi \vdash ! : \top} \quad \top\text{-I}$
$\frac{\Gamma; \Xi \vdash \text{fst}(\langle a, b \rangle) : A}{\Gamma; \Xi \vdash \text{fst}(\langle a, b \rangle) \equiv a : A} \quad \&\text{-C}_1$	$\frac{}{\Gamma \vdash 0 \text{ linear}} \quad 0\text{-F}$
$\frac{\Gamma; \Xi \vdash \text{snd}(\langle a, b \rangle) : B}{\Gamma; \Xi \vdash \text{snd}(\langle a, b \rangle) \equiv b : B} \quad \&\text{-C}_2$	$\frac{\Gamma; \Xi \vdash t : 0}{\Gamma; \Xi, \Xi' \vdash EFQ(t) : B} \quad 0\text{-E}$

Figure 6: Linear  $\multimap$ ,  $\&$ ,  $\oplus$ ,  $\top$  and  $0$  type formers

## 4.4 Linear-Cartesian interplay

We introduce two the modal operators  $M$  and  $L$ , which transfers a linear type/term to its cartesian counterpart and vice versa. Semantically, this will establish a fiberwise monoidal adjunction between the categories of linear and cartesian types:

$$\begin{array}{ccc} & L & \\ \mathcal{L}_\Gamma & \xleftarrow{\quad} & \perp \\ & M & \\ & \xrightarrow{\quad} & \mathcal{T}_\Gamma \end{array}$$

where the exponential modality from traditional linear logic is understood as the comonad  $! = LM$ . The decomposition of the exponential into an adjunction goes back to at least [1], and is given an interesting new light in [11], where it is seen as a particular case of a more general procedure of encoding structure in contexts.

Below are the syntactic rules for the operators  $M$  and  $L$ <sup>1</sup>.

$\frac{\Gamma \vdash A \text{ type}}{\Gamma \vdash A_L \text{ linear}} \quad \text{L-F}$	
$\frac{\Gamma \vdash a : A}{\Gamma; \cdot \vdash a_L : A_L} \quad \text{L-I}$	$\frac{\Gamma \vdash B \text{ linear}}{\Gamma \vdash B_M \text{ type}} \quad \text{M-F}$
$\frac{(\Gamma \vdash B \text{ linear}) \quad (\vdash \Gamma; \Xi' \text{ ctxt}) \quad \Gamma; \Xi \vdash y : A_L \quad \Gamma, x : A; \Xi' \vdash t : B}{\Gamma; \Xi, \Xi' \vdash \text{let } x \text{ be } y \text{ in } t : B} \quad \text{L-E}$	$\frac{\Gamma; \cdot \vdash b : B}{\Gamma \vdash b_M : B_M} \quad \text{M-I}$
$\frac{\Gamma; \Xi \vdash \text{let } x \text{ be } s_L \text{ in } t : B}{\Gamma; \Xi \vdash \text{let } x \text{ be } s_L \text{ in } t \equiv t[s/x] : B} \quad \text{L-C}$	$\frac{\Gamma \vdash t : B_M}{\Gamma; \cdot \vdash \sigma(t) : B} \quad \text{M-E}$
$\frac{\Gamma; y : A_L, \Xi \vdash t : B \quad (\Gamma, x : A; \Xi \vdash t[x_L/y] : B) \quad \Gamma; \Xi' \vdash a : A_L}{\Gamma; \Xi, \Xi' \vdash \text{let } x \text{ be } a \text{ in } t[x_L/y] \equiv t[a/y] : B} \quad \text{L-U}$	$\frac{\Gamma \vdash b_M : B_M}{\Gamma; \cdot \vdash \sigma(b_M) \equiv b : B} \quad \text{M-C}_1$
	$\frac{\Gamma \vdash \sigma(t)_M : B_M}{\Gamma \vdash \sigma(t)_M \equiv t : B_M} \quad \text{M-C}_2$

As a motivation for the semantic interpretation of  $L$  and  $M$  as adjoint functors given in 5.20, we will demonstrate that they already satisfy the relevant conditions from a syntactic point of view. That is, in the spirit of functional programming, we think of the cartesian and linear types (in a context  $\Gamma$ ) of our theory forming the respective categories  $\mathcal{T}$  and  $\mathcal{L}$  whose objects are types and morphisms are functions and composition is given by function composition. The identity function  $\lambda x.x : A \rightarrow A$ , yields the identity on cartesian types, while  $\lambda x.x : B \multimap B$  is the identity for linear  $B$ .

**Definition 4.1.** Define  $\hat{\circ} : (B \multimap C) \multimap (A \multimap B) \multimap (A \multimap C)$  and  $\circ : (B \rightarrow C) \rightarrow (A \rightarrow B) \rightarrow (A \rightarrow C)$  by:

$$\begin{aligned} g \hat{\circ} f &= \lambda x. g(f(x)) \\ g \circ f &= \lambda x. g(f(x)) \end{aligned}$$

**Theorem 4.2.**  $M$  is a (syntactic) functor. In other words, for any linear types,  $\Gamma \vdash A$  linear and  $\Gamma \vdash B$  linear, there is a term

$$\mathbf{fmap} : (A \multimap B)_M \rightarrow A_M \rightarrow B_M$$

such that  $\mathbf{fmap} (id_A)_M \equiv id_{A_M}$  and  $\mathbf{fmap} ((g \hat{\circ} f)_M) \equiv \mathbf{fmap} g_M \circ \mathbf{fmap} f_M$

*Proof.* Define:

$$\mathbf{fmap} f := \lambda a. (\sigma(f)\sigma(a))_M$$

and see that for  $f = (id_A)_M$ , we have  $(\sigma(id_A)\sigma(a))_M \equiv (\sigma(a))_M \equiv a : A_M$ , as well as:

$$\lambda x. (\sigma(\lambda y. g(f(y)))_M(\sigma x))_M \equiv \lambda x. (\lambda y. g(f(y))(\sigma x))_M \equiv \lambda x. (g(f(\sigma(x))))_M$$

□

Similarly, for  $L$  we have:

**Theorem 4.3.**  $L$  is a functor. i.e. for any cartesian types,  $A$  and  $B$ , there is a term  $\mathbf{fmap} : L(A \rightarrow B) \multimap (LA \multimap LB)$  such that  $\mathbf{fmap} L(id_A) \equiv id_{LA}$ .

<sup>1</sup>We have not introduced universes yet, but there is a subtlety involved with how they interact with the operators  $M$  and  $L$ , which may warrant restricting the operators  $M$  and  $L$  to only act on small types. See section 5.2.7

*Proof.* Define:

$$\text{fmap } f \ a := \text{let } \hat{f} \text{ be } f \text{ in } (\text{let } a \text{ be } y \text{ in } f(y)_L)$$

where  $\hat{f} : A \multimap B$  and  $y : A$ . When  $f = (id_A)_L$  we get:

$$\text{fmap } (id_A)_L \ a = \text{let } a \text{ be } y \text{ in } id_A(y)_L$$

which by L-U is equal to  $(id_A)_L$ .  $\square$

Furthermore, the categories of cartesian and monoidal types carry a natural monoidal structure, given by  $(\times, 1)$  and  $(\otimes, I)$ , respectively, where  $\times$  is simply  $\Sigma$  where the second argument does not depend on the first.  $M$  and  $L$  are monoidal functors with respect to these.

As our current syntactic endeavors mainly serve as motivation for the semantic interpretation of these operators, given in 5.20, we will not prove the complete statement here. We omit the naturality conditions and only prove the following:

**Theorem 4.4.** *There are terms  $t_1, t_2, t_3, t_4$ , relating the operators  $M$  and  $L$  so that the judgements:*

$$\begin{aligned} \Gamma, x : 1 &\vdash t_1 : I_M \\ \Gamma, x : A_M \times B_M &\vdash t_2 : (A \otimes B)_M \\ \Gamma; x : I &\vdash t_3 : 1_L \\ \Gamma; x : A_L \otimes B_L &\vdash t_4 : (A \times B)_L \end{aligned}$$

*hold.*

*Proof.*  $t_1$  is given by the following expression:

$$\Gamma, x : 1 \vdash *_M : I_M$$

and  $t_2$  can easily be derived:

$$\Gamma, x : A_M \times B_M \vdash (\sigma(pr_1(x)) \otimes \sigma(pr_2(x)))_M : (A \otimes B)_M$$

$t_3$  is given by:

$$\Gamma; x : I \vdash \text{let } x \text{ be } * \text{ in } \star_L : 1_L$$

$t_4$  is a bit more involved, as it requires two applications of L-E. For clarity, we display the complete proof tree of the term:

$$\begin{array}{c} \frac{\Gamma, x : A, y : B \vdash x : A}{\Gamma, x : A, y : B \vdash y : B} \\ \hline \Gamma, x : A, y : B \vdash (x, y) : A \times B \\ \hline \Gamma, x : A, y : B; \cdot \vdash (x, y)_L : (A \times B)_L \quad \Gamma, x : A; y' : B_L \vdash y' : B_L \\ \hline \text{L-E} \frac{\Gamma, x : A; y' : B_L \vdash \text{let } y \text{ be } y' \text{ in } (x, y)_L : (A \times B)_L}{\Gamma, x : A; y' : B_L \vdash \text{let } y \text{ be } y' \text{ in } (x, y)_L : (A \times B)_L} \quad \Gamma; x' : A_L \vdash x' : A_L \\ \hline \otimes\text{-E} \frac{\Gamma; x' : A_L, y' : B_L \vdash \text{let } x \text{ be } x' \text{ in } (\text{let } y \text{ be } y' \text{ in } (x, y)_L) : (A \times B)_L \quad \Gamma; z : A_L \otimes B_L \vdash z : A_L \otimes B_L}{\Gamma; z : A_L \otimes B_L \vdash \text{let } (x', y') \text{ be } z \text{ in } (\text{let } x \text{ be } x' \text{ in } (\text{let } y \text{ be } y' \text{ in } (x, y)_L)) : (A \times B)_L} \end{array}$$

$\square$

Finally, we show that  $M$  and  $L$  can be thought of as adjoint functors, in any context. In other words, we will show that there exists a “natural transformation”  $\epsilon : LM \rightarrow 1$  satisfying the following universal property:

For any  $f : L(A) \rightarrow B$ , there is a unique morphism  $g : A \rightarrow B_M$ , such that  $\epsilon_B \circ L(g) = f$ .

Translated into the syntax of our type theory, the statement becomes the following:

**Theorem 4.5** ( $L \dashv M$ ). *There is a term  $\Gamma; \beta_1 : B_{LM} \vdash \epsilon_B : B$  with the following property:*

*For any term:  $\Gamma; y : A_L \vdash f : B$ , there is a unique term  $\Gamma, x : A \vdash g : B_M$  such that  $\Gamma; y : A_L \vdash \epsilon_B[\text{let } x \text{ be } y \text{ in } g_L/\beta_1] \equiv f : B$ .*

*Proof.* The counit  $\epsilon : LM \rightarrow 1_{\mathcal{C}_\Gamma}$  is at any component  $B$  given by:

$$\begin{aligned} \Gamma, \beta_1 : B_{LM} &\vdash \beta_1 : B_{LM} \\ \Gamma, \beta_2 : B_M; \cdot &\vdash \sigma(\beta_2) : B \\ \Gamma; \beta_1 : B_{LM} &\vdash \text{let } \beta_2 \text{ be } \beta_1 \text{ in } \sigma(\beta_2) : B \end{aligned}$$

where the last line is given by applying L-E to the first and third line.

For any  $\Gamma; x : A_L \vdash f : B$ , we get the corresponding  $g$  through:

$$\begin{aligned} \Gamma, x : A &\vdash x : A \\ \Gamma, x : A; \cdot &\vdash x_L : A \\ \Gamma, x : A; \cdot &\vdash f[x_L/y] : B \\ \Gamma, x : A &\vdash f[x_L/y]_M : B_M \end{aligned}$$

making  $Lg$  the term:

$$\Gamma; y : A_L \vdash \text{let } x \text{ be } y \text{ in } f[x_L/y]_{LM} : B_{LM}$$

our composite  $\epsilon_B \circ Lg$  is given by substituting the above for  $\beta_1$  in the term corresponding to  $\epsilon_B$ , yielding:

$$\Gamma; y : A_L \vdash \text{let } \beta_2 \text{ be } (\text{let } x \text{ be } y \text{ in } f[x_L/y]_{LM}) \text{ in } \sigma(\beta_2) : B$$

Finally, if we substitute  $x_L$  for  $y$  in the above, we can rewrite the expression using L-C to:

$$\begin{aligned} \Gamma, x : A; \cdot \vdash \text{let } \beta_2 \text{ be } f_{LM} \text{ in } \sigma(\beta_2) : B &\equiv \\ \Gamma, x : A; \cdot \vdash \sigma(\beta_2)[f_M/\beta_2] &\equiv f : B \end{aligned}$$

so by L-U, we can transform this equality to the desired

$$\Gamma; y : A_L \vdash \text{let } \beta_2 \text{ be } (\text{let } x \text{ be } y \text{ in } f[x_L/y]_{LM}) \text{ in } \sigma(\beta_2) \equiv f : B$$

It remains to show that for any other term  $\Gamma; x : A \vdash h : B_M$  such that  $\epsilon_B \circ Lh = f$ , we have  $g = h$ . Syntactically,  $\epsilon_B \circ Lh = f$  corresponds to the judgement:

$$\Gamma; y : A_L \vdash \text{let } \beta_2 \text{ be } (\text{let } x \text{ be } y \text{ in } h_L) \text{ in } \sigma(\beta_2) \equiv f : B$$

If we weaken the cartesian context by  $x : A$ , we can substitute  $x_L$  for  $y$  and get:

$$\Gamma, x : A; \cdot \vdash \text{let } \beta_2 \text{ be } (\text{let } x \text{ be } x_L \text{ in } h_L) \text{ in } \sigma(\beta_2) \equiv \sigma(h) \equiv f[x_L/y] : B$$

finally, we apply  $M$  and get:

$$\Gamma, x : A \vdash \sigma(h)_M \equiv h \equiv f[x_L/y]_M : B$$

□

Since we are inclined to think of  $M$  as right adjoint, we should expect it to preserve limits. This is true, at least for product types:

**Theorem 4.6.** *For all linear types  $A$  and  $B$  in  $\Gamma$ , there is an isomorphism:*

$$\Gamma \vdash A_M \times B_M \cong (A \& B)_M$$

*Proof.* Construct a function  $f : A_M \times B_M \rightarrow (A \& B)_M$  by:

$$f \equiv \lambda x. \left( \sigma(\text{pr}_1(x)), \sigma(\text{pr}_2(x)) \right)_M$$

and  $g : (A \& B)_M \rightarrow A_M \times B_M$ :

$$g \equiv \lambda y. \left( \text{fst}(\sigma(y))_M, \text{snd}(\sigma(y))_M \right)$$

□

*which are easily seen to be mutually inverse.*

It is hard to reason about equality of linear terms since the ordinary  $Id$ -type is a dependent type, and in the theory we do not allow for type dependency on linear terms. In the presence of the  $M$  operator, however, we can form the type  $a_M = b_M$  for two terms  $\Gamma; \cdot \vdash a, b : A$ , which can serve as a surrogate for linear equality. If we add extensionality to our theory so that propositional equality implies judgemental equality, then  $a_M =_{A_M} b_M$  implies  $\Gamma; \cdot \vdash a \equiv b : A$ .

#### 4.4.1 Linear dependent types

Since we allow linear types to depend on terms of cartesian types, we can form new versions of the  $\Pi$ - and  $\Sigma$ -types. We will denote these linear variants of  $\Pi$ - and  $\Sigma$ -types by  $\sqcap$  and  $\sqsubset$ , respectively.

$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, x : A \vdash B \text{ linear}}{\Gamma \vdash \sqcap_{x:A} B \text{ linear}} \quad \sqcap\text{-F}$	$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, x : A \vdash B \text{ linear}}{\Gamma \vdash \sqsubset_{x:A} B \text{ linear}} \quad \sqsubset\text{-F}$
$\frac{\vdash \Gamma; \Xi \text{ ctxt} \quad \Gamma, x : A; \Xi \vdash b : B}{\Gamma; \Xi \vdash \lambda x. b : \sqcap_{x:A} B} \quad \sqcap\text{-I}$	$\frac{\Gamma \vdash s : A \quad \Gamma; \Xi \vdash b : B[s/x]}{\Gamma; \Xi \vdash (s, b) : \sqsubset_{x:A} B} \quad \sqsubset\text{-I}$
$\frac{\Gamma; \Xi \vdash t : \sqcap_{x:A} B \quad \Gamma \vdash a : A}{\Gamma; \Xi \vdash t(a) : B[a/x]} \quad \sqcap\text{-E}$	$\frac{\vdash \Gamma; \Xi' \text{ ctxt} \quad \Gamma \vdash C \text{ linear} \quad \Gamma; \Xi \vdash t : \sqsubset_{x:A} B \quad \Gamma, x : A; \Xi', y : B \vdash c : C}{\Gamma; \Xi, \Xi' \vdash \text{let } x, y \text{ be } t \text{ in } c : C} \quad \sqsubset\text{-E}$
$\frac{\Gamma; \Xi \vdash \lambda x. b(a) : \sqcap_{x:A} B}{\Gamma; \Xi \vdash \lambda x. b(a) \equiv b[a/x] : B[a/x]} \quad \sqcap\text{-C}$	$\frac{\Gamma; \Xi \vdash \text{let } x, y \text{ be } (s, t) \text{ in } c : C}{\Gamma; \Xi \vdash \text{let } x, y \text{ be } (s, t) \text{ in } c \equiv c[s/x][t/y] : C} \quad \sqsubset\text{-C}$

How are we to understand these types? Either in their own right (motivated by examples), as linear analogues of  $\Pi$  and  $\Sigma$  (motivated by theorem 4.7 and 4.9), or as the type theoretic analogue of quantification in linear logic. Since the free variables occurring in linear type  $B$  in the context  $\Gamma$  are precisely the variables of  $\Gamma$ , the constructs  $\sqcap$  and  $\sqcup$  can be understood as a universal or existential quantification over a variable. An example of a  $\sqcap$  type, consider for any linear type  $A$ , the  $n$ -fold tensor product  $A^n := A \otimes A \dots A$ , which we can define by induction over the natural numbers (using universes) via:

$$\begin{aligned} A^0 &:= I \\ A^{\text{succ}(n)} &:= A \otimes A^n \end{aligned}$$

with this construct, recall the example of burning hydrogen given in 3.1, now expressed as a linear function  $\text{burn} : O_2 \otimes H_2 \otimes H_2 \multimap H_2O \otimes H_2O$ . With a dependent, linear function type, we can generalize this process to the function:

$$\text{burn} : \sqcap_{n:\mathbb{N}} O_2^n \otimes H_2^{2n} \multimap H_2O^{2n}$$

An example of the  $\sqcup$  type comes from Krishnaswami's treatment of linear dependent logic as a way to model imperative programs [10]. Here, a primitive type of memory locations,  $\Gamma \vdash \text{Loc}$  type, is introduced, the terms  $x$  of which can reference a term of any cartesian type  $A$  by means of a term of the linear pointer type  $[x \mapsto A]$ :

$$\frac{\Gamma \vdash A \text{ type}}{\Gamma, x : \text{Loc} \vdash [x \mapsto A] \text{ linear}}$$

Given a location  $a : \text{Loc}$  and a term  $t : A$  in a context  $\Gamma$ , one may allocate some memory at  $a$ , and create a pointer  $a \mapsto t$  at a certain fixed cost,  $\Xi$ :

$$\frac{\Gamma \vdash t : A \quad \Gamma \vdash a : \text{Loc}}{\Gamma; \Xi \vdash a \mapsto t : [a \mapsto A]}$$

But if we want to reason more generally about our pointers, we might be interested in a more general pointer type, where the location variable is bound in a  $\sqcup$ -type. This type is formed in any context  $\Gamma$ , for any type  $A$ :

$$\frac{\Gamma \vdash A \text{ type} \quad \Gamma, x : \text{Loc} \vdash [x \mapsto A] \text{ linear}}{\Gamma \vdash \sqcup_{x:\text{Loc}} [x \mapsto A] \text{ linear}}$$

with terms introduced by:

$$\frac{\Gamma \vdash t : A \quad \Gamma \vdash a : \text{Loc} \quad \Gamma; \Xi \vdash t : [a \mapsto A]}{\Gamma; \Xi \vdash (a, t) : \sqcup_{x:\text{Loc}} [x \mapsto A]}$$

Another example takes inspiration from the realm of blockchain technology, where one deals with resources like bitcoin or ether balances. Say we model ownership of ether by a public address (generated from a cryptographic public key) having the linear type  $\text{addr}_1 : \text{ETH}$ . Then we can model a decentralized mathematical prize comittee, which give out a reward of 1 ether to whoever proves the Goldbach conjecture.

Since the reward is constant, this is not truly a dependent linear function and we abusively notate it by  $\multimap$ :

$$; x : \text{ETH} \vdash \text{GoldbachReward} : \Pi_{x:\mathbb{N}} \Sigma_{y,z:\mathbb{N}} \text{Prime}(y) \times \text{Prime}(z) \times y + z =_{\mathbb{B}} 2(\text{succ}(\text{succ}(x))) \multimap \text{ETH}$$

To execute such a function and receive the reward, one would need to exhibit that there is an address  $x$  with one ether to begin with and provide a proof of the Goldbach conjecture.

The sense in which  $\sqcap$  and  $\sqcup$  are "linear analogues" of  $\Pi$  and  $\Sigma$  can be formalized in the following way:

**Theorem 4.7.** *For all  $\Gamma \vdash A$  type and  $\Gamma, x : A \vdash B$  linear, there is an isomorphism:*

$$\Pi_{x:A} B_M \cong (\sqcap_{x:A} B)_M$$

*Proof.* Construct the function

$$h := \lambda f. (\lambda x. \sigma(f(x)))_M : \Pi_{x:A} B_M \rightarrow (\sqcap_{x:A} B)_M$$

and in the other direction:

$$h^{-1} := \lambda g. \lambda y. (\sigma(g)(y))_M : (\sqcap_{x:A} B)_M \rightarrow \Pi_{x:A} B_M$$

which are mutually inverse:

$$\begin{aligned} h \circ h^{-1} &:= \lambda \alpha. \lambda f. (\lambda x. \sigma(f(x)))_M \left( \lambda g. \lambda y. (\sigma(g)(y))_M \right) (\alpha) \equiv \\ &\lambda \alpha. \lambda f. (\lambda x. \sigma(f(x)))_M (\lambda y. (\sigma(\alpha)(y))_M) \equiv \\ &\lambda \alpha. \left( \lambda x. \sigma \left( (\lambda y. (\sigma(\alpha)(y))_M)(x) \right) \right)_M \equiv \\ &\lambda \alpha. \left( \lambda x. \sigma \left( (\sigma(\alpha)(x))_M \right) \right)_M \equiv \\ &\lambda \alpha. (\lambda x. \sigma(\alpha)(x))_M \equiv \lambda \alpha. \alpha \end{aligned}$$

$$\begin{aligned}
h^{-1} \circ h &:= \lambda\alpha.(\lambda g.\lambda y.(\sigma(g)(y)))_M \left( \lambda f.(\lambda x.\sigma(f(x)))_M \right) (\alpha) \equiv \\
&\lambda\alpha.(\lambda g.\lambda y.(\sigma(g)(y)))_M (\lambda x.\sigma(\alpha(x)))_M \equiv \\
&\lambda\alpha.\lambda y.(\sigma((\lambda x.\sigma(\alpha(x)))_M)(y))_M \equiv \\
&\lambda\alpha.\lambda y.(\lambda x.\sigma(\alpha(x))(y))_M \equiv \\
&\lambda\alpha.\lambda y.(\sigma(\alpha(y)))_M \equiv \\
&\lambda\alpha.\lambda y.\alpha(y) \equiv \lambda\alpha.\alpha
\end{aligned}$$

□

Similarly, assuming some extra *commuting conversions* and uniqueness rules, we can display a linear isomorphism:

$$(\Sigma_{x:A} B)_L \cong_{\sqsubset_{x:A}} B_L$$

By a linear isomorphism, we mean a pair of linear functions  $j : (\Sigma_{x:A} B)_L \multimap_{\sqsubset_{x:A}} B_L$  and  $j^{-1} : \sqsubset_{x:A} B_L \multimap (\Sigma_{x:A} B)_L$  such that  $j \circ j^{-1} = id$  and  $j^{-1} \circ j = id$ .

A common practice in linear type theory is to assume a collection of rules which allows permuting the eliminator terms of various type formers in a controlled manner. For example, following ??, we define *environments* recursively in the following way:

**Definition 4.8.** An **environment**  $E[\_]$ , is an object defined recursively as follows:

$$\begin{aligned}
E[\_] &:= \text{let } * \text{ be } E[\_] \text{ in } t \mid \text{let } * \text{ be } t \text{ in } E[\_] \mid t \otimes E[\_] \mid E[\_] \otimes t \mid \\
&\text{let } x, y \text{ be } E[\_] \text{ in } t \mid \text{let } x, y \text{ be } t \text{ in } E[\_] \mid \lambda x.E[\_] \mid E[\_]t \parallel (E[\_], t) \mid \\
&\mid (t, E[\_]) \mid tE[\_] \mid (E[\_])_L \mid \text{let } x \text{ be } E[\_] \text{ in } t \mid \text{let } x \text{ be } t \text{ in } E[\_]
\end{aligned}$$

We can then consider the addition of the following commuting conversions:

- For environments  $E[\_]$ :

$$\frac{\Gamma; \Xi \vdash \text{let } * \text{ be } t \text{ in } E[u] : A}{\Gamma; \Xi \vdash \text{let } * \text{ be } t \text{ in } E[u] \equiv E[\text{let } * \text{ be } t \text{ in } u]} \text{ CC-I}$$

- For environments  $E[\_]$  that do not bind  $x$  or  $y$ :

$$\frac{\Gamma; \Xi \vdash \text{let } x, y \text{ be } t \text{ in } E[u] : A}{\Gamma; \Xi \vdash \text{let } x, y \text{ be } t \text{ in } E[u] \equiv E[\text{let } x, y \text{ be } t \text{ in } u] : A} \text{ CC-}\otimes/\sqsubset$$

- For environments  $E[\_]$  that do not bind  $x$ :

$$\frac{\Gamma; \Xi \vdash \text{let } x \text{ be } t \text{ in } E[u] : A}{\Gamma; \Xi \vdash \text{let } x \text{ be } t \text{ in } E[u] \equiv E[\text{let } x \text{ be } t \text{ in } u] : A} \text{ CC-L}$$

Unfortunately, since we cannot reasonably decide on a direction for these judgemental equalities, the addition of commuting conversions like these makes us unable to construct a term rewriting procedure for our type theory. Therefore, we will not assume them in general, but only for results like the following:

**Theorem 4.9.** Assuming the commuting conversions above, and the following uniqueness rule for  $\sqsubset$ :

$$\frac{\Gamma; \Xi \vdash \text{let } x, y \text{ be } t \text{ in } (x, y) : A}{\Gamma; \Xi \vdash \text{let } x, y \text{ be } t \text{ in } (x, y) \equiv t : A} \sqsubset\text{-}U$$

there is an isomorphism

$$(\Sigma_{x:A} B)_L \cong_{\sqsubset_{x:A}} B_L$$

*Proof.* We first construct the linear function  $j : (\Sigma_{x:A} B)_L \multimap_{\sqsubset_{x:A}} B_L$  by:

$$j := \lambda f.\text{let } p \text{ be } f \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) : (\Sigma_{x:A} B)_L \multimap_{\sqsubset_{x:A}} B_L$$

and its inverse,  $j^{-1}$ , by:

$$\frac{\Gamma; q : \sqsubset_{x:A} B_L \vdash q : \sqsubset_{x:A} B_L \quad \frac{\Gamma; x : A; y : B_L \vdash y : B_L \quad \frac{\Gamma; x : A, z : B \vdash x : A \quad \Gamma; x : A, z : B \vdash z : B}{\Gamma; x : A, z : B \vdash (x, z) : \Sigma_{x:A} B}}{\Gamma; x : A, z : B; \cdot \vdash (x, z)_L : (\Sigma_{x:A} B)_L}}{\Gamma; q : \sqsubset_{x:A} B_L \vdash \text{let } x, y \text{ be } q \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) : (\Sigma_{x:A} B)_L} \quad \frac{\Gamma; q : \sqsubset_{x:A} B_L \vdash q : \sqsubset_{x:A} B_L \quad \Gamma; x : A; y : B_L \vdash \text{let } z \text{ be } y \text{ in } (x, z)_L : (\Sigma_{x:A} B)_L}{\Gamma; \cdot \vdash \lambda q.\text{let } x, y \text{ be } q \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) : \sqsubset_{x:A} B_L \multimap (\Sigma_{x:A} B)_L}$$

and see that:

$$\begin{aligned}
j \circ j^{-1} &:= \lambda\alpha.\lambda f.\text{let } p \text{ be } f \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) (\lambda q.\text{let } x, y \text{ be } q \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L)) \alpha \equiv \\
&\lambda\alpha.\lambda f.\text{let } p \text{ be } f \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) (\text{let } x, y \text{ be } \alpha \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L)) \equiv \\
&\lambda\alpha.\text{let } p \text{ be } (\text{let } x, y \text{ be } \alpha \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L)) \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) \equiv (\text{CC-L}) \\
&\lambda\alpha.\text{let } x, y \text{ be } \alpha \text{ in } \left( \text{let } p \text{ be } (\text{let } z \text{ be } y \text{ in } (x, z)_L) \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) \right) \equiv (\text{CC-L}) \\
&\lambda\alpha.\text{let } x, y \text{ be } \alpha \text{ in } \left( \text{let } p \text{ be } (\text{let } z \text{ be } y \text{ in } (x, z))_L \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) \right) \equiv (\text{CC-L}) \\
&\lambda\alpha.\text{let } x, y \text{ be } \alpha \text{ in } \left( \text{let } p \text{ be } (x, \text{let } z \text{ be } y \text{ in } z)_L \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right) \right) \equiv (\text{L-C} + \Sigma\text{-C}) \\
&\lambda\alpha.\text{let } x, y \text{ be } \alpha \text{ in } \left( x, (\text{let } z \text{ be } y \text{ in } z)_L \right) \equiv (\text{CC-L}) \\
&\lambda\alpha.\text{let } x, y \text{ be } \alpha \text{ in } \left( x, (\text{let } z \text{ be } y \text{ in } z_L) \right) \equiv (\text{L-U} + \sqsubset\text{-U}) \\
&\lambda\alpha.\alpha
\end{aligned}$$

and in the other direction:

$$\begin{aligned}
j^{-1} \circ j &:= \lambda\alpha.\lambda q.\text{let } x, y \text{ be } q \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) (\lambda f.\text{let } p \text{ be } f \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right)) \alpha \equiv \\
&\lambda\alpha.\lambda q.\text{let } x, y \text{ be } q \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) (\text{let } p \text{ be } \alpha \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right)) \equiv \\
&\lambda\alpha.\text{let } x, y \text{ be } (\text{let } p \text{ be } \alpha \text{ in } \left( \text{pr}_1(p), (\text{pr}_2(p))_L \right)) \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) \equiv (\text{CC-L}) \\
&\lambda\alpha.\text{let } p \text{ be } \alpha \text{ in } \left( \text{let } x, y \text{ be } (\text{pr}_1(p), \text{pr}_2(p)_L) \text{ in } (\text{let } z \text{ be } y \text{ in } (x, z)_L) \right) \equiv \sqsubset\text{-C} \\
&\lambda\alpha.\text{let } p \text{ be } \alpha \text{ in } \left( (\text{let } z \text{ be } \text{pr}_2(p)_L \text{ in } (\text{pr}_1(p), z)_L) \right) \equiv \text{L-C} \\
&\lambda\alpha.\text{let } p \text{ be } \alpha \text{ in } \left( (\text{pr}_1(p), \text{pr}_2(p))_L \right) \equiv (\Sigma\text{-U}) + (\text{L-U}) \\
&\lambda\alpha.\alpha
\end{aligned}$$

□

As outlined in section 5.2, the semantics of the type formers  $\Pi$ ,  $\sqcap$  and  $\Sigma$ ,  $\sqsubset$  are as left and right adjoints to reindexing functors respectively, which can by lemma 6.2 be constructed via limits and colimits, these results reflect the fact that the left adjoint  $L$  preserves colimits and the right adjoints  $M$  preserves limits.

## 4.5 Universes

Our cartesian and linear types live in separate universes,  $U$  and  $L$ . Since linear types are type checked in a purely cartesian context, the linear universe is a cartesian type. This suggests that there is no need for more than one linear universe. To simplify the semantics, we also only assume one cartesian and one linear universe, rather than an infinite cumulative hierarchy, where  $El(U_i) : U_{i+1}$ , even though this might be more appealing from a syntactic point of view. Our universes are given á la Tarski and are closed under all previously introduced type formers. Below, we only outline the closure over the type formers  $\Pi$ ,  $\otimes$  and  $\sqcap$ , but this should be sufficient to give the idea. For more detail we refer to Hofmann's *Syntax and Semantics of Dependent types*, [6], or Krishnaswami's *Integrating Linear and Dependent types*, [10].

$$\begin{array}{c}
\frac{\vdash \Gamma \text{ ctxt}}{\Gamma \vdash L \text{ type}} \text{ L-F} \\
\\
\frac{\vdash \Gamma \text{ ctxt}}{\Gamma \vdash U \text{ type}} \text{ U-F} \\
\\
\frac{\Gamma \vdash t : U}{\Gamma \vdash El(t) \text{ type}} \text{ U-El-F} \\
\\
\frac{\Gamma \vdash t : U \quad \Gamma, x : El(t) \vdash v : U}{\Gamma \vdash \hat{\Pi}_{x:El(t)} v : U} \text{ U-}\Pi \\
\\
\frac{\Gamma \vdash t : U \quad \Gamma, x : El(t) \vdash v : U}{\Gamma \vdash El(\hat{\Pi}_{x:El(t)} v) \equiv \Pi_{x:El(t)} El(v)} \text{ U-}\Pi\text{-Ty} \\
\\
\frac{\Gamma \vdash t : L}{\Gamma \vdash El(t) \text{ linear}} \text{ L-El-F} \\
\\
\frac{\Gamma \vdash t : L \quad \Gamma \vdash s : L}{\Gamma \vdash t \hat{\otimes} s : L} \text{ L-}\otimes \\
\\
\frac{\Gamma \vdash t : L \quad \Gamma \vdash s : L}{El(t \hat{\otimes} s) \equiv El(s) \otimes El(t)} \text{ L-}\otimes\text{-Ty} \\
\\
\frac{\Gamma \vdash t : U \quad \Gamma, x : El(t) \vdash s : L}{\Gamma \vdash \hat{\Gamma}_{x:El(t)} s : L} \text{ L-}\Pi \\
\\
\frac{\Gamma \vdash t : U \quad \Gamma, x : El(t) \vdash s : L}{\Gamma \vdash El(\hat{\Gamma}_{x:El(t)} s) \equiv \sqcap_{x:El(t)} El(s)} \text{ L-}\Pi\text{-Ty}
\end{array}$$

As an example using universes, we can properly formulate the identity function of cartesian or linear types by:

$$\begin{aligned}
& \text{id} : \Pi_{A:\mathcal{U}} A \rightarrow A \\
& \text{id } A \ a \equiv a
\end{aligned}$$

or

$$\begin{aligned}
& \text{id} : \sqcap_{A:\mathcal{L}} A \multimap A \\
& \text{id } A \ a \equiv a
\end{aligned}$$

respectively. It also allows us to formulate the type of "pointed linear types":

$$\Gamma \vdash \sqsubset_{A:\mathcal{L}} A \text{ linear}$$

## 5 Semantics

### 5.1 Structural semantic core

To explore the models of linear dependent type theory we begin by constructing a categorical structure which abstracts the key features of the theory. We will utilize the notion of a *comprehension category*, which provides the most general structure in which we can deal with the structural rules like context extensions and substitutions. Once this has been taken care of we may consider what extra conditions have to be imposed in order for the model to support various type constructors, and then provide concrete models that satisfy these conditions.

There are only two type constructors that will be assumed in the general semantic structure: the linear tensor product and unit. This simplifies the core semantics by allowing us to use symmetric monoidal categories instead of multicategories when interpreting linear types.

The idea behind the core of the semantics is to construct a comprehension category [8], consisting of a base category of contexts, a 'cartesian' fibration consisting of cartesian types equipped with context extensions, and a lax symmetric monoidal fibration consisting of linear types.

**Definition 5.1.** A **comprehension category** consists of a commutative diagram of functors

$$\begin{array}{ccc}
\mathcal{T} & \xrightarrow{\pi} & \mathcal{C}^{\rightarrow} \\
& \searrow p & \downarrow \text{cod} \\
& & \mathcal{C}
\end{array}$$

where  $B^{\rightarrow}$  is the arrow category of  $B$  and  $\text{cod} : B^{\rightarrow} \rightarrow B$  denotes the codomain functor such that:

1.  $\mathcal{C}$  has a terminal object
2.  $p : \mathcal{T} \rightarrow \mathcal{C}$  is a Grothendieck fibration,

3.  $\pi : \mathcal{T} \rightarrow \mathcal{C}^\rightarrow$  takes cartesian morphisms in  $\mathcal{T}$  to cartesian morphisms in  $\mathcal{C}^\rightarrow$

Notice that by the second condition, cartesian morphisms in  $\mathcal{T}$  are mapped to pullback squares in  $\mathcal{C}$ :

A cartesian morphism  $(p, q) : f \rightarrow g$  in  $\mathcal{C}^\rightarrow$  is a commutative square in  $\mathcal{C}$

$$\begin{array}{ccc} B & \xrightarrow{g} & B' \\ p \downarrow & & \downarrow q \\ A & \xrightarrow{f} & A' \end{array}$$

such that for any  $E', E, q' : E' \rightarrow B', e : E \rightarrow E'$  and  $p' : E \rightarrow A$  as in the following diagram:

$$\begin{array}{ccc} E & \xrightarrow{e} & E' \\ id_E \downarrow & & \downarrow q' \\ E & \xrightarrow{q'e} & B' \\ p' \downarrow & & \downarrow q \\ A & \xrightarrow{f} & A' \end{array}$$

there is a unique arrow  $u : E \rightarrow B$  such that  $p' = p \circ u$  and  $q'e = g \circ u$ . This is precisely the universal property of the pullback. If  $\mathcal{C}$  has all pullbacks, then  $\text{cod} : \mathcal{C}^\rightarrow \rightarrow \mathcal{C}$  is a fibration and we immediately have a comprehension category. Maps of  $\mathcal{C}$  that arise via  $\pi(A)$  for some  $A \in \mathcal{T}$  will be called *projections*, and by the remark above, pullbacks of projections always exist. Terms of a type will be interpreted as sections of the corresponding projections and pullbacks of  $\mathcal{C}$  will play the role of substitutions. Here we need to be careful, however:

**Remark 5.2.** On Coherence. A subtlety often overlooked in the construction of models of type theory are the various issues arising from the fact that from a categorical point of view, it is natural to consider objects up to isomorphism, whereas in type theory we speak of equality “on the nose” [5]. In particular, when interpreting substitution as a pullback, we need to take into account that, in the syntax, substitution is strictly functorial, while pullbacks, in general, are not. For example, the pullback of  $f$  along  $g \circ h$  is *isomorphic to* the pullback of  $\pi_1$  along  $h$ , below, but not necessarily equal to it.

$$\begin{array}{ccc} A \times_C B' \cong (A \times_C B) \times_C B' & \xrightarrow{\quad} & B' \\ \downarrow & & \downarrow h \\ A \times_C B & \xrightarrow{\pi_1} & B \\ \downarrow \pi_2 & & \downarrow g \\ A & \xrightarrow{f} & C \end{array}$$

This problem can generally be overcome by showing that there exists a suitable choice of pullbacks such that this isomorphism is an equality, and this is essentially why we are forcing our comprehension category to come equipped with liftings of every map in the base category, so that our fibration is *split*. In fact, every comprehension category is equivalent to a strict one, and if a full comprehension category supports various type formers, then these will also be supported in the corresponding split version. [12]

In dealing with linear dependent type theory, we run into a similar problem. Equipped with a (lax) monoidal fibration,  $q : \mathcal{L} \rightarrow \mathcal{C}$ , we will interpret linear contexts  $\Xi = a_1 : A_1, a_2 : A_2 \dots a_n : A_n$  over a cartesian context  $\Gamma$  as the tensor product  $[[\Xi]] = [[A_1]] \otimes [[A_2]] \dots \otimes [[A_n]]$  in the monoidal category  $\mathcal{L}_\Gamma$ . The weakening of a linear context  $\Xi$ , as given by the rule:

$$\frac{\vdash \Gamma; \Xi \text{ ctxt} \quad \Gamma \vdash A \text{ type}}{\vdash \Gamma, x : A; \Xi \text{ ctxt}} \quad \text{C-Weak}$$

will be interpreted as the image of the object  $[[\Xi]] \in \mathcal{L}_\Gamma$  under the functor  $\pi_A^* : \mathcal{L}_\Gamma \rightarrow \mathcal{L}_{\Gamma.A}$  induced by the projection morphism  $\pi_A : \Gamma.A \rightarrow \Gamma$  in the base. But in general, we do not have an equality of  $\pi_A^*(A) \otimes \pi_A^*(B)$  and  $\pi_A^*(A \otimes B)$ . To accommodate this discrepancy, we introduce the notion of a split monoidal fibration:

**Definition 5.3.** A **split monoidal fibration** is a lax monoidal fibration  $q : \mathcal{L} \rightarrow \mathcal{C}$ , equipped with a cleavage  $\{u^*, \bar{u}\}_{u \in \mathcal{C}}$ , so that every lift  $u^*$  is a strict monoidal functor,  $u^*v^* = (vu)^*$  and  $1_\Gamma^* = 1_{\mathcal{L}_\Gamma}$  for for all compatible liftings  $u^*$  and  $v^*$  and objects  $\Gamma \in \mathcal{C}$ .

Notice that this condition is quite strong, as the induced functors of a lax monoidal fibration are generally only lax monoidal. This disqualifies the graph fibration ?? from constituting a model of our type theory. However, every lax monoidal fibration where the induced functors are strong will be equivalent to a split monoidal fibration. Equipped with these notions, we define the general structure of the structural core of our type theory:

**Definition 5.4.** A model for linear dependent type theory consists of a split comprehension category  $p : \mathcal{T} \rightarrow \mathcal{C}$  and a split monoidal fibration  $q : \mathcal{L} \rightarrow \mathcal{C}$ , as illustrated in the following picture:

$$\begin{array}{ccc} \mathcal{L} & & \mathcal{T} \xrightarrow{\pi} \mathcal{C}^{\rightarrow} \\ & \searrow q & \downarrow p \quad \swarrow \text{cod} \\ & & \mathcal{C} \end{array}$$

Before showing how this structure supports the structural rules of the theory, the following lemma will come in handy:

**Lemma 5.5.** The pullback of an arrow,  $g$ , has a section if  $g$  does. In other words, given a pullback of  $g$ :

$$\begin{array}{ccc} A \times_C B & \xrightarrow{k} & B \\ \downarrow g^* & & \downarrow \begin{pmatrix} g & h \end{pmatrix} \\ A & \xrightarrow{f} & C \end{array}$$

such that  $gh = 1_C$ , then  $h^*$  exists and is a section of  $g^*$ .

*Proof.* Since  $A$  with projections  $1_A$  and  $hf$  forms a cone to the cospan, there exists a unique map  $u : A \rightarrow A \times_C B$  such that  $hfu = k$  and  $g^*u = 1_A$ , making  $u$  a section of  $g^*$ .  $\square$

We prove soundness by defining an interpretation function by induction on the derivation rules of Figure 2.

**Theorem 5.6** (Soundness). *A split comprehension category  $p : \mathcal{T} \rightarrow \mathcal{C}$  together with a split monoidal fibration  $q : \mathcal{L} \rightarrow \mathcal{C}$  is a model for the linear dependent type theory consisting of the structural rules presented in Figure 2.*

*Proof.* We construct an interpretation function  $[[\cdot]]$ , which sends:

- Cartesian contexts  $\Gamma$  to objects of  $\mathcal{C}$ , considered up to definitional equality and renaming of bound variables.
- Linear contexts  $\Xi$  in  $\Gamma$  to objects of  $\mathcal{L}_{[[\Gamma]]}$ .
- Cartesian types  $A$  in  $\Gamma$  to objects of  $\mathcal{T}_{[[\Gamma]]}$ .
- Linear types  $B$  in  $\Gamma$  to objects of  $\mathcal{L}_{[[\Gamma]]}$ .
- Cartesian terms  $M : A$  in  $\Gamma$  to sections of  $\pi([A]) : [[\Gamma, A]] \rightarrow [[\Gamma]]$ .
- Linear terms  $b : B$  in  $\Gamma; \Xi$  to morphisms  $[[b]] : [[\Xi]] \rightarrow [[B]]$ .

Proceeding by induction on the derivation rules, we will often abuse notation slightly and denote semantic objects the same as their syntactic counterparts.

- Case of CI-Base:  $[[\cdot]]$  is the terminal object  $\mathbf{1}$  of  $\mathcal{C}$ .
- Case of CM-Base:  $[[\cdot; \cdot]]$  is the unit of  $\mathcal{L}_1$ .
- Case of C-int-ext: By the induction hypothesis, we are given  $A$  in  $\mathcal{T}_\Gamma$  and need to display an object  $\Gamma.A$  in  $\mathcal{C}$ . This object is the domain of the morphism that  $A$  is mapped to via  $\pi$ :

$$\Gamma.A \xrightarrow{\pi_A} \Gamma$$

- Case of C-lin-ext: Given objects  $[[\Xi]]$  and  $[[A]]$  in  $\mathcal{L}_{[[\Gamma]]}$ , the extended context  $\Gamma; \Xi, x : A$  is interpreted as the object  $[[\Xi]] \otimes [[A]] \in \mathcal{L}_{[[\Gamma]]}$ .
- Case of C-weak-1: Given  $A, \Delta \in \mathcal{T}_\Gamma$ , we send  $\Delta$  through the functor  $\pi_A^* : \mathcal{T}_\Gamma \rightarrow \mathcal{T}_{\Gamma.A}$  induced by lifting the morphism  $\pi_A : \Gamma.A \rightarrow \Gamma$ . The resulting object  $\pi_A^*(\Delta)$  will be sent to the context  $p(\pi_A^*(\Delta)) = \Gamma.A.\Delta\{\pi_A\}$  via  $p$ , which is the interpretation of the conclusion of the rule C-weak-1.
- Case of C-weak-2: Notice that since  $\pi$  is a cartesian functor, the context above fits into the following pullback:

$$\begin{array}{ccc} \Gamma.A.\Delta\{\pi_A\} & \xrightarrow{q} & \Gamma.\Delta \\ \downarrow \pi_{\Delta\{\pi_A\}} & & \downarrow \pi_\Delta \\ \Gamma.A & \xrightarrow{\pi_A} & \Gamma \end{array}$$

so by lifting  $q$  to the monoidal functor  $q^* : \mathcal{L}_{\Gamma.\Delta} \rightarrow \mathcal{L}_{\Gamma.A.\pi^*(\Delta)}$ . The context we are looking for is the image of  $\Xi$  under this functor.

- Case of C-lin-ext: For objects  $\Xi$  and  $A$  in  $\mathcal{L}_\Gamma$ , we let their tensor product  $\Xi \otimes A$  denote the extended context  $\Gamma; \Xi, x : A$ .
- Case of Lin-exch. Since our lax monoidal fibration is symmetric, we have  $\Xi \otimes A \otimes B \otimes \Xi' \cong \Xi \otimes B \otimes A \otimes \Xi'$  in  $\mathcal{L}_\Gamma$ . Applying exchange to a judgement corresponds to composing with this isomorphism.

- Case of Weak-L. For any  $A \in \mathcal{T}_\Gamma$  and morphism  $t : \Xi \rightarrow A$  in  $\mathcal{L}_{\Gamma, \Gamma'}$ , we can transfer  $t$  along the functor  $q_{A, \Gamma}^* : \mathcal{L}_{\Gamma, \Gamma'} \rightarrow \mathcal{L}_{\Gamma.A, \Gamma'\{\pi_A\}}$  induced by the map  $q_{A, \Gamma'}$  arising from the following pullback diagram:

$$\begin{array}{ccc} \Gamma.A.\Gamma'\{\pi_A\} & \xrightarrow{\quad} & \Gamma.\Gamma' \\ \downarrow q_{A, \Gamma'} & & \downarrow \pi'_\Gamma \\ \Gamma.A & \xrightarrow{\pi_A} & \Gamma \end{array}$$

to yield a morphism  $q_{A, \Gamma'}^*(t) : q_{A, \Gamma'}^*(\Xi) \rightarrow q_{A, \Gamma'}^*(A')$ .

- Case of Weak-I. The morphism  $q_{A, \Gamma'}$  above also induces a functor  $q_{A, \Gamma'}^* : \mathcal{T}_{\Gamma, \Gamma'} \rightarrow \mathcal{T}_{\Gamma.A, \Gamma'\{\pi_A\}}$ .
- For Int-subst-1, the judgement  $\mathcal{J}$  can take three forms:

$$\begin{aligned} \mathcal{J} &= B[M/x] \text{ type} \\ \mathcal{J} &= b[M/x] : B[M/x] \\ \mathcal{J} &= B[M/x] \text{ linear} \end{aligned}$$

The corresponding categorical structure work by way of relating substitution in the theory to pullbacks in  $\mathcal{C}$ . We begin with showing that there is a type  $B[M/x]$  in the context  $\Gamma.\Gamma'[M/x]$ .

Suppose we are given the following objects of  $\mathcal{T}$ :

$$\begin{aligned} A &\in \mathcal{T}_\Gamma \\ \Gamma' &\in \mathcal{T}_{\Gamma.A} \\ B &\in \mathcal{T}_{\Gamma.A.\Gamma'} \end{aligned}$$

and a section:

$$M : \Gamma \rightarrow \Gamma.A$$

of the projection  $\pi_A$ . We first lift  $M$  to a cartesian arrow  $M^* : \Gamma.\Gamma'\{M\} \rightarrow \Gamma'$ , which is sent to the following pullback square by  $\pi$ :

$$\begin{array}{ccc} \Gamma.\Gamma'\{M\} & \xrightarrow{q_{(M, \Gamma')}} & \Gamma.A.\Gamma' \\ \downarrow \pi_{\Gamma'\{M^*\}} & & \downarrow \pi_{\Gamma'} \\ \Gamma & \xrightarrow{M} & \Gamma.A \end{array}$$

where  $q_{(M, \Gamma')}$  is some map whose existence is given by the structure of the comprehension. We then lift  $q_{(M, \Gamma')}$  to obtain a cartesian arrow  $q_{(M, \Gamma')}^* : \Gamma.\Gamma'\{M^*\}.B\{q_{(M, \Gamma')}^*\} \rightarrow \Gamma.A.\Gamma'.B$  which fits in the following pullback diagram:

$$\begin{array}{ccc} \Gamma.\Gamma'\{M^*\}.B\{q_{(M, \Gamma')}^*\} & \xrightarrow{q_{(q_{(M, \Gamma')}, B)}} & \Gamma.A.\Gamma'.B \\ \downarrow \pi_{B\{q_{(M, \Gamma')}^*\}} & & \downarrow \pi_B \\ \Gamma.\Gamma'\{M^*\} & \xrightarrow{q_{(M, \Gamma')}} & \Gamma.A.\Gamma' \end{array}$$

The element  $\Gamma.\Gamma'\{M^*\}.B\{q_{(M, \Gamma')}^*\}$  of  $\mathcal{T}_{\Gamma.\Gamma'\{M^*\}}$  along with its associated projection will be our interpretation of  $\Gamma.\Gamma'[M/x] \vdash B[M/x]$ .

Now suppose there is a section  $b : \Gamma.A.\Gamma' \rightarrow \Gamma.A.\Gamma'.B$  of the projection  $\pi_B$ . To display an element of  $B[M/x]$  is to give a section of  $\pi_{B\{q_{(M, \Gamma')}^*\}}$ . By lemma 5.5, we get such a section by pulling back  $b$  along  $q_{(q_{(M, \Gamma')}, B)}$ .

Finally, if  $B$  is an object of  $\mathcal{L}_{\Gamma.A, \Gamma'}$ , then the image of  $B$  under the functor  $q_{(M, \Gamma')}^* : \mathcal{L}_{\Gamma.A, \Gamma'} \rightarrow \mathcal{L}_{\Gamma.\Gamma'\{M^*\}}$  will be our interpretation of  $B[M/x]$  as a linear type in the context  $\Gamma, \Gamma[M/x]$ .

- Case of Int-subst-2. The interpretation of Int-subst-2 is the image of  $t$  under  $q_{(M, \Gamma')}^*$ .
- Case of Lin-subst. Given morphisms  $t : \Xi \otimes A \rightarrow B$  and  $M : \Xi' \rightarrow A$  we get a morphism  $t \circ (id_\Xi \otimes M) : \Xi \otimes \Xi' \rightarrow B$ . Precomposing with the isomorphism  $\otimes \Xi, \Xi' \cong \Xi \otimes \Xi'$  yields the desired morphism  $\otimes \Xi, \Xi' \rightarrow B$ .
- Case of Int-var. For any  $A \in \mathcal{T}_\Gamma$ ,  $\Gamma.A$  together with its identity map forms a cone to the cospan:

$$\begin{array}{ccc} & \Gamma.A & \\ & \downarrow \pi_A & \\ \Gamma.A & \xrightarrow{\pi_A} & \Gamma \end{array}$$

so by the universal mapping property of the pullback, there is a unique morphism  $v_A : \Gamma.A \rightarrow \Gamma.A.A\{\pi_A\}$  such that  $\pi_{A\{\pi_A\}} v_A = 1_{\Gamma.A}$ . This map is thus the interpretation of the judgement  $\Gamma, x : A \vdash x : A$ .

- Case of Lin-var. The morphism corresponding to the linear variable term  $\Gamma; x : A \vdash x : A$  is given by the identity morphism on  $A$  in  $\mathcal{L}_\Gamma$ .

□

## 5.2 Semantic type formers

In the following, we assume that the comprehension category comprising the core of our syntax is full, i.e. that the functor  $\pi : \mathcal{T} \rightarrow \mathcal{C}^\rightarrow$  is full and faithful. This allows us to think of homsets  $\mathcal{T}_\Gamma(A, B)$  as living over the base category projections  $\mathcal{C}_\Gamma(\pi_A : \Gamma.A \rightarrow \Gamma, \pi_B : \Gamma.B \rightarrow \Gamma)$ .

**Definition 5.7.** A **model of LD TT** is a full, split comprehension category  $\pi : \mathcal{T} \rightarrow \mathcal{C}^\rightarrow$  and a split monoidal fibration  $q : \mathcal{L} \rightarrow \mathcal{C}$ .

It will sometimes be useful to also assume that the comprehension category has a *unit*, as this will give rise to an isomorphism  $\mathcal{C}_{/\Gamma}(\Gamma.A, \Gamma.B) \cong \mathcal{T}_{\Gamma.A}(1, \pi_A^*(B))$  [8].

**Definition 5.8.** A fibration  $p : \mathcal{T} \rightarrow \mathcal{C}$  **admits a terminal object** if there is a functor  $\mathbf{1} : \mathcal{C} \rightarrow \mathcal{T}$ , such that for every  $\Gamma \in \mathcal{C}$ ,  $\mathbf{1}(\Gamma)$  is a terminal object of the fiber  $\mathcal{T}_\Gamma$ , and for every  $f : \Delta \rightarrow \Gamma$ , the canonical map  $\alpha : f^*(\mathbf{1}(\Gamma)) \rightarrow \mathbf{1}(\Delta)$  is an isomorphism.

As a result of this definition, the functor  $\mathbf{1}$  is full and faithful.

**Definition 5.9.** A comprehension category  $\pi : \mathcal{T} \rightarrow \mathcal{C}^\rightarrow$  **has a unit** if the fibration  $p : \mathcal{T} \rightarrow \mathcal{C}$  admits a terminal object functor  $\mathbf{1}$  which is left adjoint to the functor  $s(\pi) : \mathcal{T} \rightarrow \mathcal{C}$ , selecting the source of the morphism assigned by  $\pi$ .

Most of our models will naturally be equipped with such a structure, and this yields the nice property that  $\mathcal{C}_{/\Gamma}(\Gamma.A, \Gamma.B) \cong \mathcal{T}_{\Gamma.A}(1, \pi_A^*(B))$ , allowing us to shift in perspective to think of terms depending on  $\Gamma$  and  $A$  as either living in the slice category  $\mathcal{C}_{/\Gamma}$  or in the fiber  $\mathcal{T}_{\Gamma.A}$ . Importantly, since  $\mathbf{1}$  is full and faithful, the unit of the adjunction is a natural isomorphism, so for every  $A \in \mathcal{T}_\Gamma$ , we have  $\eta_A : \Gamma.A \cong \Gamma.A.1$ .

### 5.2.1 Basic linear types

**Definition 5.10.** A model of LD TT **supports I-types** if, for every  $\Gamma$ , there exists an object  $[[I]] \in \mathcal{L}_\Gamma$ , equipped with a morphism  $[[*]] : I \rightarrow [[I]]$ , such that for every pair of maps  $t : \Xi' \rightarrow [[I]]$  and  $c : \Xi \rightarrow C$ , there exists a map  $[[\text{let } t \text{ be } * \text{ in } c]] : \bigotimes \Xi, \Xi' \rightarrow C$  such that  $[[\text{let } * \text{ be } * \text{ in } c]] = c$ .

This is trivially satisfied by every model by setting  $[[I]] = I$ ,  $[[*]] = 1_I$ , and  $[[\text{let } t \text{ be } * \text{ in } c]]$  to the composite  $\rho(c \otimes [[t]])\alpha : \bigotimes \Xi, \Xi' \cong \Xi \otimes \Xi' \rightarrow C \otimes I \cong C$ , where  $\rho$  is the right unitor for the monoidal structure of  $\mathcal{L}_\Gamma$ , and  $\alpha$  is the isomorphism  $\bigotimes \Xi, \Xi' \cong \Xi \otimes \Xi$ . As for the identity  $\rho(c \otimes 1_I)\alpha = c$ , notice that  $\alpha : \bigotimes \Xi \cong \Xi \otimes [[\cdot]] = \Xi \otimes I$  is given by  $\rho^{-1}$ , so we get  $\rho(c \otimes 1_I) = c\rho$ , from the naturality of  $\rho$ .

**Definition 5.11.** A model of LD TT **supports  $\otimes$ -types**, if, for every  $A, B \in \mathcal{L}_\Gamma$ , there exists an object  $[[A \otimes B]] \in \mathcal{L}_\Gamma$ , such that for any arrows  $a : \Xi \rightarrow A$ ,  $b : \Xi' \rightarrow B$ , there exists an arrow  $[[a \otimes b]] : \bigotimes \Xi, \Xi' \rightarrow [[A \otimes B]]$  and for arrows  $t : \Xi' \rightarrow [[A \otimes B]]$  and  $c : \bigotimes \Xi \otimes A \otimes B \rightarrow C$ , there exists an arrow  $[[\text{let } x \otimes y \text{ be } t \text{ in } c : C]]$  such that  $[[\text{let } x \otimes y \text{ be } a \otimes b \text{ in } c]] = c$ .

Again, it is not hard to see that there is a canonical interpretation of this in any model of LD TT sending  $[[A \otimes B]]$  to  $[[A]] \otimes [[B]]$ . Some care is needed in order to always make sure contexts are left associated.

Similarly, one can define what it means for a model of LD TT to support  $\multimap, \&, \oplus, \top$  and  $0$ . We may think of these conditions as corresponding to weak versions of internal homs, binary products and coproducts, and terminal and initial object of the fibers, that are stable under reindexing functors. Therefore, whenever the fibers of our model are monoidal closed, complete or cocomplete, we know that it supports the corresponding type formers. This is well established and not the focus of the interplay between linear and dependent types we explore here. For a more detailed treatment we refer the reader to [13].

### 5.2.2 $\Pi$ and $\Sigma$

What it means for a model of linear dependent type theory to *support*  $\Pi$ -types is directly inherited from the standard, non-linear case.

**Definition 5.12.** A model of LD TT **supports  $\Pi$ -types** if, for all  $A \in \mathcal{T}_\Gamma$ , the induced functor  $\pi_A^* : \mathcal{T}_\Gamma \rightarrow \mathcal{T}_{\Gamma.A}$  has a right adjoint  $\Pi_A : \mathcal{T}_{\Gamma.A} \rightarrow \mathcal{T}_\Gamma$  satisfying the following Beck-Chevalley condition: For all pullbacks in  $\mathcal{C}$ :

$$\begin{array}{ccc} \Gamma.E & \xrightarrow{q_{E,E'}} & \Delta.E' \\ \downarrow \pi_E & & \downarrow \pi_{E'} \\ \Gamma & \xrightarrow{f} & \Delta \end{array} \quad (1)$$

inducing the following functors between fibers:

$$\begin{aligned} q_{E,E'}^* &: \mathcal{T}_{\Delta,E'} \rightarrow \mathcal{T}_{\Gamma,E} \\ f^* &: \mathcal{T}_{\Delta} \rightarrow \mathcal{T}_{\Gamma} \\ \Pi_E &: \mathcal{T}_{\Gamma,E} \rightarrow \mathcal{T}_{\Gamma} \\ \Pi_{E'} &: \mathcal{T}_{\Delta,E'} \rightarrow \mathcal{T}_{\Delta} \end{aligned}$$

The canonical natural transformation  $f^* \Pi_{E'} \rightarrow \Pi_E q_{E,E'}^*$  induced by the adjunction is a natural isomorphism.

The Beck-Chevalley condition is in effect saying that substitution commutes with the  $\Pi$ -type. For example, if  $E' = E[\bar{t}/\bar{y}]$ , with the map  $f^*$  representing the substitution  $[\bar{t}/\bar{y}]$ , then the Beck-Chevalley condition reads that for all  $B \in \mathcal{T}_{\Gamma}$ , we have  $(\Pi_{x:E} B)[\bar{t}/\bar{y}] \cong \Pi_{x:E[\bar{t}/\bar{y}]} B[\bar{t}/\bar{y}]$ .

As the rules  $\Sigma$  contains one more eliminator than usual ( $\Sigma$ -E<sub>2</sub> in Figure 3), one might wonder whether this requires additional conditions for the semantic type formers to ensure that these are well behaved with respect to the linear fibers. We will shortly see that this is not the case.

**Definition 5.13.** A model of LD $\mathcal{T}$ T **supports  $\Sigma$ -types** if it satisfies the following:

1. For all  $A \in \mathcal{T}_{\Gamma}$ , the induced functor  $\pi_A^* : \mathcal{T}_{\Gamma} \rightarrow \mathcal{T}_{\Gamma,A}$  has a left adjoint,  $\Sigma_A$ ,
2. such that for all pullbacks (as in 1), these satisfy the Beck-Chevalley condition, i.e. the natural transformation:  $\Sigma_E q^* \rightarrow f^* \Sigma_{E'}$  is a natural isomorphism, and
3. the induced map  $pair_{A,B} : \Gamma.A.B \rightarrow \Gamma.\Sigma_A B$  is an isomorphism

The map  $pair_{A,B} : \Gamma.A.B \rightarrow \Gamma.\Sigma_A B$  such that  $\pi_{\Sigma_A B} pair_{A,B} = \pi_A \pi_B$ , arises as the image of the unit  $\eta : B \rightarrow \pi_A^*(\Sigma_A B)$  in  $\mathcal{T}_A$  under the comprehension functor  $\pi : \mathcal{T} \rightarrow \mathcal{C}^{\rightarrow}$ . The inverse of the pairing map will be denoted  $(pr_1, pr_2) : \Gamma.\Sigma_A B \rightarrow \Gamma.A.B$ .

This structure is sufficient to support new elimination rule ( $\Sigma$ -E<sub>2</sub>):

**Theorem 5.14.** *If a model of LD $\mathcal{T}$ T supports  $\Sigma$ -types, then for every object  $C \in \mathcal{L}_{\Gamma.\Sigma_A B}$  and morphism  $c : \Xi \rightarrow C\{pair_{A,B}\}$  in  $\mathcal{L}_{\Gamma.A.B}$  and section  $s : \Gamma \rightarrow \Gamma.\Sigma_A B$ , there exists a morphism  $\hat{c}_s : \Xi\{(pr_1, pr_2)\} \rightarrow C\{s\}$  such that given sections  $a : \Gamma \rightarrow \Gamma.A$  and  $b : \Gamma.A \rightarrow \Gamma.A.B$ , then  $\hat{c}_{(a,b)} = c\{ba\} : \Xi\{ba\} \rightarrow C\{ba\}$ .*

*Proof.* The situation is illustrated in the following diagram:

$$\begin{array}{ccc} & & (pr_1, pr_2) \\ & \swarrow & \searrow \\ \Gamma.A.B & \xrightarrow{pair_{A,B}} & \Gamma.\Sigma_A B \\ \downarrow \pi_{A,B} & & \swarrow \pi_{\Sigma_A B} \\ \Gamma & & \end{array}$$

Let  $\hat{c}_s = c\{((pr_1, pr_2)s)\}$ . First, this morphism has the correct target since we have

$$C\{((pr_1, pr_2)s)\}\{pair_{A,B}\} = C\{(pair_{A,B}(pr_1, pr_2)s)\} = C\{s\}$$

, relying on the fact our lax monoidal fibration is split. Secondly, we need to show that given sections  $a : \Gamma \rightarrow \Gamma.A$  and  $b : \Gamma.A \rightarrow \Gamma.A.B$ , we have  $c\{((pr_1, pr_2)(a, b))\} = c\{a\}\{b\}$ :

$$\{(pr_1, pr_2)(a, b)\} = \{(pr_1, pr_2)pair_{A,B}ba\} = \{ba\} = \{a\}\{b\}$$

□

We may also speak of a model **supporting simple products**, which simply correspond to products in the fibers of  $\mathcal{T}$  which are stable under reindexing functors. These are of course implied if the model supports  $\Sigma$ -types.

### 5.2.3 Identity types

When it comes to Id-types, the situation is not as fortunate. If one wants to keep the theory intensional, we need to add condition (3) to make sure that the semantic identity types satisfy the added elimination and computation rule, =-E<sub>2</sub> and =-C<sub>2</sub> in Figure 4.

**Definition 5.15** (Id-types). A model of LD $\mathcal{T}$ T **supports Id-types** if, for all  $A \in \mathcal{T}_{\Gamma}$ , there exists an object  $Id_A \in \mathcal{T}_{\Gamma.A.A\{\pi_A\}}$  and a morphism  $r_A : \Gamma.A \rightarrow \Gamma.A.A\{\pi_A\}.Id_A$  such that:

1. The following diagram commutes:

$$\begin{array}{ccc} \Gamma.A & & \\ \downarrow r_A & \searrow v_A & \\ \Gamma.A.A\{\pi_A\}.Id_A & \xrightarrow{\pi_{Id_A}} & \Gamma.A.A\{\pi_A\} \end{array}$$

2. For any commutative diagram:

$$\begin{array}{ccc} \Gamma.A & \xrightarrow{\quad} & \Delta.C \\ \downarrow r_A & & \downarrow \pi_C \\ \Gamma.A.A\{\pi_A\}.Id_A & \xrightarrow{\quad} & \Delta \end{array}$$

there exists a lift  $J : \Gamma.A.A\{\pi_A\}.Id_A \rightarrow \Delta.C$  making the two triangles commute.

3. For any pair of objects,  $C, \Xi \in \mathcal{L}_{\Gamma.A.A+.Id}$ , sections  $M, N : \Gamma \rightarrow \Gamma.A$ ,  $P : \Gamma \rightarrow \Gamma.Id_A\{N^+\}\{M\}$ , and morphism  $c : \Xi\{r_A\} \rightarrow C\{r_A\}$ , there exists a morphism  $\hat{c}_{[M,N,P]} : \Xi\{P^+\}\{N^+\}\{M\} \rightarrow C\{P^+\}\{N^+\}\{M\}$  such that  $\hat{c}_{[M,M,ref]} = c\{M\}$ .

If one were to work within an extensional type theory, where judgemental and propositional equality coincide, the third condition is always satisfied:

**Definition 5.16.** A model of linear dependent type theory supports **extensional identity types** if there are objects  $Id_A$  and morphisms  $r_A$  satisfying condition (1) and (2) such that for sections  $M, N : \Gamma \rightarrow \Gamma.A$  the existence of a section  $P : \Gamma \rightarrow \Gamma.Id_A\{M\}\{N^+\}$  implies  $N = M$ .

**Theorem 5.17.** *Support for extensional identity types implies support for identity types, in other words, extensional identity types always satisfy condition (3) of definition 5.15*

*Proof.* We will show that when  $M = N$ , the morphism  $P^+N^+M : \Gamma \rightarrow \Gamma.A.A\{\pi_A\}.Id_A$  is equal to  $r_A M : \Gamma \rightarrow \Gamma.A.A\{\pi_A\}.Id_A$ . This implies that the morphism  $\hat{c}_{[M,N,P]} : \Xi\{P^+\}\{N^+\}\{M\} \rightarrow C\{P^+\}\{N^+\}\{M\}$  of defintion 5.15 really is just  $c\{M\} : \Xi\{M\}\{r_A\} \rightarrow C\{M\}\{r_A\}$ .

The section  $N^+ : \Gamma.A \rightarrow \Gamma.A.A\{\pi_A\}$  appearing arises as in lemma 5.5 from the following pullback:

$$\begin{array}{ccc} \Gamma.A.A\{\pi_A\} & \xrightarrow{\quad} & \Gamma.A \\ \pi_A\{\pi_A\} \left( \begin{array}{c} \uparrow \\ \downarrow \end{array} \right)_{N^+} & & \pi_A \left( \begin{array}{c} \uparrow \\ \downarrow \end{array} \right)_N \\ \Gamma.A & \xrightarrow{\pi_A} & \Gamma \end{array}$$

while  $P^+N^+M : \Gamma \rightarrow \Gamma.A.A\{\pi_A\}.Id_A$  the composite  $q_{[M,N],\pi_{Id_A}} \circ P$  in the following commutative square:

$$\begin{array}{ccc} \Gamma.Id_A\{N^+\}\{M\} & \xrightarrow{q_{[M,N],\pi_{Id_A}}} & \Gamma.A.A\{\pi_A\}.Id_A \\ \left( \begin{array}{c} \uparrow \\ \downarrow \end{array} \right)_P & & \downarrow \pi_{Id_A} \\ \Gamma & \xrightarrow{N^+M} & \Gamma.A.A\{\pi_A\} \end{array}$$

But with extensional identity types, we have  $M = N$ . This implies that  $v_A M = M^+M$ , as these are both maps from  $\Gamma$  into the pullback  $\Gamma.A.A\{\pi_A\}$  such that  $\pi_A\{\pi_A\}v_A M = \pi_A\{\pi_A\}M^+M = M$  as illustrated below:

$$\begin{array}{ccccc} & & \Gamma & & \\ & & \downarrow M & & \downarrow M \\ & & \Gamma.A.A\{\pi_A\} & \xrightarrow{\quad} & \Gamma.A \\ & & \downarrow \pi_A\{\pi_A\} & & \downarrow \pi_A \\ \Gamma & \xrightarrow{v_A M = M^+M} & \Gamma.A & \xrightarrow{\pi_A} & \Gamma \end{array}$$

This makes  $\Gamma$  a cone to the previous pullback:

$$\begin{array}{ccccc} & & \Gamma & & \\ & & \downarrow P & & \downarrow r_A M \\ & & \Gamma.Id_A\{N^+\}\{M\} & \xrightarrow{q_{[M,N],\pi_{Id_A}}} & \Gamma.A.A\{\pi_A\}.Id_A \\ & & \downarrow 1_\Gamma & & \downarrow \pi_{Id_A} \\ \Gamma & \xrightarrow{N^+M = v_A M} & \Gamma & \xrightarrow{\quad} & \Gamma.A.A\{\pi_A\} \end{array}$$

forcing  $r_A M = P N^+ M$ . □

### 5.2.4 $\sqcap$ - and $\sqcup$ -types

The semantic type formers for the linear dependent  $\sqcap$  and  $\sqcup$  is akin to that of  $\Pi$  and  $\Sigma$ . They are given by adjoints to the functors between fibers of  $\mathcal{L}$  induced by the projection maps in  $\mathcal{C}$ .

**Definition 5.18.** A model of LD TT **supports  $\sqcap$ -types** if, for all  $A \in \mathcal{T}_\Gamma$ , the induced monoidal functor  $\pi_A^* : \mathcal{L}_\Gamma \rightarrow \mathcal{L}_{\Gamma.A}$  has a monoidal right adjoint,  $\sqcap_A$  satisfying the following Beck-Chevalley condition:  
For all pullback squares in  $\mathcal{C}$  of the following form:

$$\begin{array}{ccc} \Gamma.E & \xrightarrow{q_{E,E'}} & \Delta.E' \\ \downarrow \pi_E & & \downarrow \pi_{E'} \\ \Gamma & \xrightarrow{f} & \Delta \end{array}$$

, the canonical natural transformation  $f^* \sqcap_{E'} \rightarrow \sqcap_E q_{E,E'}^*$  is a natural isomorphism.

**Definition 5.19.** It **supports  $\sqcup$ -types** if, for all  $A \in \mathcal{T}_\Gamma$ , the functor every  $\pi_A^*$  has a monoidal left adjoint, satisfying the following:

1. (Beck-Chevalley): For all pullbacks squares as above, the natural transformation  $\sqcup_E q^* \rightarrow f^* \sqcup_{E'}$  is a natural isomorphism.
2. (Frobenius reciprocity): For all objects  $\Xi \in \mathcal{L}_\Gamma$  and  $B \in \mathcal{L}_{\Gamma.A}$ , the canonical morphism  $\sqcup_A (\Xi \{ \pi_A \} \otimes B) \rightarrow \Xi \otimes \sqcup_A B$  is an isomorphism.

To illustrate why these conditions form the appropriate semantic counterpart to the derivation rules, we will outline the case for  $\sqcup$  in detail.

For every object  $B \in \mathcal{L}_{\Gamma.A}$ , we get a type  $\sqcup_A B \in \mathcal{L}_\Gamma$ , such that, given any section  $s : \Gamma \rightarrow \Gamma.A$ , and map  $b : \Xi \rightarrow B\{s\}$  in  $\mathcal{L}_\Gamma$ , we get a map:

$$s^* \eta_B \circ b : \Xi \rightarrow B\{s\} \rightarrow s^* \pi_A^* (\sqcup_A B) = \sqcup_A B$$

where  $\eta_B : B \rightarrow \pi^* (\sqcup_A B)$  is the unit of the adjunction. This map is the interpretation of the term  $(s, b)$  given by the introduction rule  $\sqcup$ -I.

To interpret the elimination rule, we are given maps  $t : \Xi \rightarrow \sqcup_A B$  in  $\mathcal{L}_\Gamma$  and  $c : \Xi' \{ \pi_A \} \otimes B \rightarrow C \{ \pi_A \}$  in  $\mathcal{L}_{\Gamma.A}$ . By the adjunction, there exists a map  $\hat{c} : \sqcup_A (\Xi' \{ \pi_A \} \otimes B) \rightarrow C$  such that  $\eta_{\Xi' \{ \pi_A \} \otimes B} \circ \pi_A^* \hat{c} = c$ . By the Frobenius reciprocity condition, we have an isomorphism:  $\beta_{\Xi', B} : \Xi' \otimes \sqcup_A B \rightarrow \sqcup_A (\Xi' \{ \pi_A \} \otimes B)$ , and we get a map:

$$\hat{c} \beta : \Xi' \otimes \sqcup_A B \cong \sqcup_A (\Xi' \{ \pi_A \} \otimes B) \rightarrow C$$

which we can precompose with  $1_{\Xi'} \otimes t$  to get a map from  $\Xi' \otimes \Xi$  to  $C$ . We can then precompose with an appropriate isomorphism  $\alpha' : \otimes (\Xi', \Xi) \rightarrow \Xi' \otimes \Xi$  to get a map from  $\otimes \Xi', \Xi$  to  $C$ , which will be the interpretation of the elimination term from the rule  $\sqcup$ -E.

The computation rule boils down to showing that the following triangle commutes:

$$\begin{array}{ccc} \{s\}(\Xi' \{ \pi_A \} \otimes B) & & \\ \downarrow s^* \eta_{(\Xi' \{ \pi_A \} \otimes B)} & \searrow s^* c & \\ s^* \pi_A^* \sqcup_A (\Xi' \{ \pi_A \} \otimes B) = \sqcup_A (\Xi' \{ \pi_A \} \otimes B) & \xrightarrow{\hat{c}} & C \end{array}$$

which follows from applying the functor  $s^*$  to the equality  $\eta_{\Xi' \{ \pi_A \} \otimes B} \circ \pi_A^* \hat{c} = c$ .

### 5.2.5 The operators $M$ and $L$

**Definition 5.20.** A model of LD TT with unit **supports the operators  $M$  and  $L$**  if there exists functors  $M : \mathcal{L} \leftrightarrow \mathcal{T} : L$  which are cartesian with respect to the fibrations  $p : \mathcal{T} \rightarrow \mathcal{C}$  and  $q : \mathcal{L} \rightarrow \mathcal{C}$ , such that  $L \dashv M$  is a fibred adjunction and there is an isomorphism of hom-sets:

$$\mathcal{L}_{\Gamma.A}(\pi_A^* (\Xi'), \pi_A^* (B)) \cong \mathcal{L}_\Gamma(LA \otimes \Xi', B)$$

Recall that a fibred adjunction implies that there are natural isomorphisms making the following diagram commute:

$$\begin{array}{ccc}
\mathcal{L}_\Gamma & \begin{array}{c} \xleftarrow{L_\Gamma} \\ \xrightarrow{M_\Gamma} \end{array} & \mathcal{T}_\Gamma \\
\downarrow \pi_A^*(\mathcal{L}) & & \downarrow \pi_A^*(\mathcal{T}) \\
\mathcal{L}_{\Gamma.A} & \begin{array}{c} \xleftarrow{L_{\Gamma.A}} \\ \xrightarrow{M_{\Gamma.A}} \end{array} & \mathcal{T}_{\Gamma.A}
\end{array}$$

which from a syntactic perspective ensures that  $M$  and  $L$  commute with substitution.

The final condition of the definition is what yields the elimination and computation rules L-U, and while it might appear somewhat unnatural semantically, it does turn out to hold automatically in a large class of models, due to the following result:

**Theorem 5.21.** *In a model of LDTT that supports  $\multimap$  type formers, then any fibred adjunction  $L \dashv M$  where  $L(1) \cong I$  satisfies  $\mathcal{L}_{\Gamma.A}(\pi_A^*(\Xi'), \pi^*(B)) \cong \mathcal{L}_\Gamma(LA \otimes \Xi', B)$ .*

*Proof.* A model supporting internal homs must have reindexing functions which preserve these. That is, we have an isomorphism  $\pi_A^*[\Xi, B] \cong [\pi_A^*\Xi, \pi_A^*B]$ . We get a chain of isomorphisms:

$$\begin{aligned}
& \mathcal{L}_\Gamma(LA \otimes \Xi, B) \cong \\
& \mathcal{L}_\Gamma(LA, [\Xi, B]) \cong \\
& \mathcal{T}_\Gamma(A, M_\Gamma[\Xi, B]) \cong \\
& \mathcal{T}_{\Gamma.A}(1, \pi_A^*(M_\Gamma[\Xi, B])) \cong \\
& \mathcal{T}_{\Gamma.A}(1, M_{\Gamma.A}\pi_A^*[\Xi, B]) \cong \\
& \mathcal{L}_{\Gamma.A}(L_{\Gamma.A}(1), \pi_A^*[\Xi, B]) \cong \\
& \mathcal{L}_{\Gamma.A}(I, \pi_A^*[\Xi, B]) \cong \\
& \mathcal{L}_{\Gamma.A}(I, [\pi_A^*\Xi, \pi_A^*B]) \cong \\
& \mathcal{L}_{\Gamma.A}(\pi_A^*\Xi, \pi_A^*B).
\end{aligned}$$

□

## 5.2.6 Universes

There are various degrees to which a model can support universes. The baseline condition is an object  $U$  in every fiber such there is an object in the same fiber for every section of the corresponding projection. In order to even state what it means for a universe to be closed under various types, we need to assume that our model supports such types.

**Definition 5.22.** A model of LDTT **supports cartesian universes**, if for every  $\Gamma \in \mathcal{C}$ , there exists an object  $U \in \mathcal{T}_\Gamma$ , such that, for every section  $t : \Gamma \rightarrow \Gamma.U$  to the corresponding projection, there exists an object  $El(t) \in \mathcal{T}_\Gamma$ . For a model that supports the type former in question, the universe is closed under:

- $\Pi$ -types, (or  $\Sigma$ ) if, for sections  $t : \Gamma \rightarrow \Gamma.U$  and  $v : \Gamma.El(t) \rightarrow \Gamma.El(t).U$ , there is a section  $\hat{\Pi}_{El(t)}v : \Gamma \rightarrow \Gamma.U$  such that  $El(\hat{\Pi}_{El(t)}) = \Pi_{El(t)}El(v)$  (or  $\Sigma$ ) i.e. if the object corresponding to  $\hat{\Pi}_{El(t)}v$  is equal the image of  $El(v)$  under the functor corresponding to the semantic type former.
- $Id$ -types, if, for sections  $A : \Gamma \rightarrow \Gamma.U$ ,  $a, b : \Gamma \rightarrow \Gamma.El(A)$ , there is a section  $\hat{Id}(a, b) : \Gamma \rightarrow \Gamma.U$ , such that  $El(\hat{Id}(a, b)) = Id_A$ .

Linear universes are defined in the same fashion, keeping in mind that the linear universe is a cartesian type.

**Definition 5.23.** A model of LDTT **supports linear universes**, if, for every  $\Gamma \in \mathcal{C}$ , there is an object  $L \in \mathcal{T}_\Gamma$ , such that for every section  $t : \Gamma \rightarrow \Gamma.L$  to the corresponding projection, there exists an object  $El(t)$  in  $\mathcal{L}_\Gamma$ . For a model that supports the type former in question, the linear universe is closed under this type if:

- $I$ , (or  $\top$ ,  $0$ ): There is a section  $\hat{I} : \Gamma \rightarrow \Gamma.L$ , such that  $El(\hat{I}) = I$  in  $\mathcal{L}_\Gamma$ .
- $\otimes$  (or  $\multimap$ ,  $\&$ ): For every pair of sections  $a, b : \Gamma \rightarrow \Gamma.L$ , there is a section  $a \hat{\otimes} b$  (or  $\hat{\multimap}$ ,  $\hat{\&}$ ) such that  $El(a \hat{\otimes} b) = El(a) \otimes El(b)$

**Definition 5.24.** Given a model supporting both cartesian and linear universes, these are closed under:

- $M$ , if, for every section  $x : \Gamma \rightarrow \Gamma.L$ , there exists an element  $\hat{M}(x) : \Gamma \rightarrow \Gamma.U$  such that  $El(\hat{M}(x)) = M(El(x))$ .
- $L$ , if, for every section  $x : \Gamma \rightarrow \Gamma.U$ , there exists an element  $\hat{L}(x) : \Gamma \rightarrow \Gamma.L$  such that  $El(\hat{L}(x)) = L(El(x))$ .
- $\sqcap$  (or  $\sqcup$ ), if, for sections  $t : \Gamma \rightarrow \Gamma.U$  and  $s : \Gamma.El(t) \rightarrow \Gamma.El(t).L$ , there exists a section  $\hat{\sqcap}_{El(t)}s : \Gamma \rightarrow \Gamma.L$  (or  $\hat{\sqcup}$ ), such that  $El(\hat{\sqcap}_{El(t)}s) = \sqcap_{El(t)}El(s)$ .

### 5.2.7 Universes and small type formers

We have not said anything about which types we expect to be contained in our universes. As they stand, the axioms of in section 4.5 do not postulate that there are any inhabitants of  $L$  or  $U$  to begin with. One could imagine restating the type formation rules to be defined with respect to universes, an approach exemplified by [10]. As tempting as it is to think of any cartesian type being an element of  $U$ , this would imply  $El(U) : U$ , which is begging for Russels paradox to yield an inconsistency of the theory. Asking for every linear type to belong to  $L$  is a more reasonable requirement, since the linear universe is a cartesian type. But doing this forces us to restrict the operators  $M$  and  $L$  so as to only act on small types.

**Definition 5.25.** In a model that supports cartesian universes, let the category  $small(\mathcal{T})$  of **small cartesian types** be the full subcategory of  $\mathcal{T}$  whose objects are  $El(t)$  for some section  $t : \Gamma \rightarrow \Gamma.U$  in some context  $\Gamma$ .

**Definition 5.26.** Similarly, we define the category  $small(\mathcal{L})$  of **small linear types** to be the full subcategory of  $\mathcal{L}$  whose objects are  $El(t)$  for some section  $t : \Gamma \rightarrow \Gamma.L$  in some context  $\Gamma$ .

**Definition 5.27.** If there is a full subcategory  $small(\mathcal{C})$  of  $\mathcal{C}$  such that the restriction of the functors  $p, q$  and  $\pi$  of a model of linear dependent type theory:

$$\begin{array}{ccc} \mathcal{L} & & \mathcal{T} \xrightarrow{\pi} \mathcal{C}^{\rightarrow} \\ & \searrow q & \downarrow p \quad \swarrow cod \\ & & \mathcal{C} \end{array}$$

to the categories  $small(\mathcal{L})$  and  $small(\mathcal{T})$  has  $small(\mathcal{C})$  as its codomain, so that:

$$\begin{array}{ccc} small(\mathcal{L}) & & small(\mathcal{T}) \xrightarrow{\pi} small(\mathcal{C})^{\rightarrow} \\ & \searrow q & \downarrow p \quad \swarrow cod \\ & & small(\mathcal{C}) \end{array}$$

is a model of linear dependent type theory, we call this a **submodel of small types**.

We can now define what it means for a model to support small versions of various type formers.

**Definition 5.28.** We say that a model of linear dependent type theory **supports  $M$  and  $L$  for small types**, if it supports  $M$  and  $L$  for a submodel of small types.

Syntactically, this corresponds to changing the type formation rules of  $M$  and  $L$  so as to not be defined for all types, but only those who are contained in the cartesian and linear universes:

$$\frac{\Gamma \vdash A : L}{\Gamma \vdash A_M : U} \text{ M-F-U} \quad \frac{\Gamma \vdash A : U}{\Gamma \vdash A_L : L} \text{ L-F-U}$$

Similarly, we can define support for small  $\Box$  and  $\sqsubset$  as support for  $\Box$  and  $\sqsubset$  in a submodel of small types.

**Definition 5.29.** We say that the linear universe  $L$  is **all-encompassing** if the category of small linear types and  $\mathcal{L}$  coincide.

## 6 Models

### 6.1 Set indexed families

Our first model will be based on the standard set-theoretic interpretation of dependent type theory [6]. The extension of this model to the linear realm is fairly straightforward, and provides a good springboard for examples to come. (It is also sufficient for showing that linear dependent type theory is a proper generalisation of both dependent type theory and linear type theory, as outlined in [17].)

Our linear and cartesian fibrations will both be constructed as fibrations of set indexed families:

**Definition 6.1** ( $Fam(\mathcal{C})$ ). For an arbitrary category  $\mathcal{C}$ , let  $Fam(\mathcal{C})$  denote the category whose objects consists of pairs  $(S, f)$  where  $S$  is a set and  $f$  is a function  $f : S \rightarrow Ob(\mathcal{C})$ . Morphisms of  $Fam(\mathcal{C})$  are pairs  $(u, \alpha) : (S, f) \rightarrow (S', g)$  where  $u : S \rightarrow S'$  and  $\alpha : S \rightarrow Mor(\mathcal{C})$  such that  $\alpha(s) : f(s) \rightarrow g(u(s))$  for all  $s \in S$ . Composition is given, for two compatible morphisms  $(u, \alpha)$  and  $(v, \beta)$ , by:

$$(v, \beta) \circ (u, \alpha) = (v \circ u, g(u(s)) \circ f(s))$$

for all  $s \in S$ .

By projecting a family to its indexing set, we get a fibration  $p : Fam(\mathcal{C}) \rightarrow \mathbf{Set}$ , and if  $\mathcal{C}$  has a terminal object,  $\top$  such that the hom-sets  $\mathcal{C}(\top, A)$  are small for all  $A \in \mathcal{C}$ , we can form a comprehension category with unit by defining  $\pi : Fam(\mathcal{C}) \rightarrow \mathbf{Set}^\rightarrow$  as follows.

On objects, let

$$\pi(S, f) = fst : \{(s, t) \mid s \in S, t : \top \rightarrow f(s)\} \rightarrow S$$

For a morphism  $(u, \alpha) : (S, f) \rightarrow (S', g)$ , let

$$q_{(u, \alpha)} : \{(s, t) \mid s \in S, t : \top \rightarrow f(s)\} \rightarrow \{(s', t') \mid s' \in S', t' : \top \rightarrow g(s')\}$$

be defined by  $q_{(u, \alpha)}(s, t) = (u(s), \alpha(s) \circ t)$ . The functor  $\pi$  sends morphisms  $(u, \alpha)$  to squares:

$$\begin{array}{ccc} \{(s, t) \mid s \in S, t : \top \rightarrow f(s)\} & \xrightarrow{q_{(u, \alpha)}} & \{(s', t') \mid s' \in S', t' : \top \rightarrow g(s')\} \\ \downarrow fst & & \downarrow fst \\ S & \xrightarrow{u} & S' \end{array}$$

in  $\mathbf{Set}$ . This comprehension category will be full if the global sections functor  $\mathcal{C}(\top, -) \rightarrow \mathbf{Set}$  is full and faithful.

For a morphism  $u : S \rightarrow p(S', f) = S'$  the canonical choice of a lift  $u^* = (u, i) : (S, fu) \rightarrow (S', f)$  where  $i : S \rightarrow Mor(\mathcal{C})$  is defined by  $s \mapsto 1_{fu(s)}$  makes this a split fibration.

The cartesian part of our semantic structure will simply be the fibration  $p : Fam(\mathbf{Set}) \rightarrow \mathbf{Set}$  with  $\pi : Fam(\mathbf{Set}) \rightarrow \mathbf{Set}^\rightarrow$  as outlined above. Then for any symmetric monoidal category  $\mathcal{V}$  we form a lax monoidal fibration by letting the unit object be given at any fiber by mapping a set  $S$  to the family constant at the unit of  $\mathcal{V}$ , and define the tensor product as:

$$(S, g) \otimes (S, f) = (S, f \otimes g) = (S, \lambda s. f(s) \otimes g(s))$$

For  $u : S \rightarrow p(S', f) = S'$  in the base, we have:

$$u^*((S', \alpha) \otimes (S', \beta)) = (S, \lambda s. \alpha u(s) \otimes \beta(u(s))) = u^*(S', \alpha) \otimes u^*(S', \beta)$$

Since the tensor product is defined pointwise, it is preserved by reindexing functors, so this is in fact a split monoidal fibration. Putting this together, this forms our first concrete model of the type theory:

$$\begin{array}{ccccc} Fam(\mathcal{V}) & & Fam(\mathbf{Set}) & \xrightarrow{\pi} & \mathbf{Set}^\rightarrow \\ & \searrow q & \downarrow p & \swarrow cod & \\ & & \mathbf{Set} & & \end{array}$$

This model trivially supports  $\otimes$  and  $I$ -types (all models do). For any fibration  $p : Fam(\mathcal{C}) \rightarrow \mathbf{Sets}$ , its fiberwise limits and colimits are constructed pointwise, so they exist if and only if they do in  $\mathcal{C}$ . Since reindexing functors is simply precomposition, they preserve these (co)limits. We therefore get that the families model supports the type formers  $\oplus, 0, \&$  and  $\top$  if  $\mathcal{V}$  has binary coproducts, initial object, binary products and terminal object respectively. Similarly, it supports  $\multimap$  if  $\mathcal{V}$  is monoidal closed, by  $[(S, f), (S, g)] = (S, \lambda s. [f(s), g(s)])$ . This is a right adjoint to  $\otimes$ , since at every component, the set of maps  $f(s) \otimes g(s) \rightarrow h(s)$  is isomorphic to  $f(s) \rightarrow [g(s), h(s)]$ .

For the dependent types, we utilize the following result:

**Theorem 6.2.** For a fibration  $p : Fam(\mathcal{C}) \rightarrow \mathbf{Sets}$  and a function  $u : S \rightarrow S'$  in the base,  $u^* : Fam(\mathcal{C})_{S'} \rightarrow Fam(\mathcal{C})_S$  has a left (right) adjoints if and only if  $\mathcal{C}$  has small coproducts (products).

*Proof.* For  $\mathcal{C}$  with small coproducts, define the left adjoint to  $u^*$  by  $(S, f) \mapsto (S', \lambda s'. \prod_{s \in u^{-1}(s')} f(s))$ . Similarly for  $\mathcal{C}$  with small products, define a right adjoint to  $u^*$  by  $(S, f) \mapsto (S', \lambda s'. \prod_{s \in u^{-1}(s')} f(s))$ .

In the other direction, the set of objects we want to take the (co)product of forms a family  $A = \{A_i\}$  in  $Fam(\mathcal{C})$ . The lift of the unique map  $! : p(A) \rightarrow \mathbf{1}$  in the base has a right (left) adjoint, making  $\Pi_!(A)$  an object of  $Fam(\mathcal{C})_1 \cong \mathcal{C}$ , so that for every object  $B \in \mathcal{C}$ , we have:

$$\mathcal{C}(B, \Pi_!(A)) \cong Fam(\mathcal{C})_S(!^*B, A)$$

where  $!^*B = (S, \lambda s.B)$ . This means that every map on the right hand side, which consists of a family of morphisms  $f_i : B \rightarrow A_i$  gives rise to a unique map on the left hand side, which is precisely the universal property of the product.  $\square$

Since reindexing functors of  $Fam(\mathcal{C})$  are simply given by precomposition, adjoints to reindexing functors always satisfy Beck-Chevalley condition:

**Theorem 6.3.** *If every lift  $f^* : Fam(\mathcal{C})_S \rightarrow Fam(\mathcal{C})_{S'}$  has a right adjoint  $G_{f^*}$ , defined as in Theorem 6.2, then, for all objects  $A = (\Gamma, a)$  and pullbacks of the following form:*

$$\begin{array}{ccc} \Gamma'.f^*\{A\} & \xrightarrow{q_{A,f}} & \Gamma.A \\ \downarrow \pi_{f^*\{A\}} & & \downarrow \pi_A \\ \Gamma' & \xrightarrow{f} & \Gamma \end{array}$$

there is a natural isomorphism  $\eta : G_{\pi_A^*} f^* \cong q_{A,f}^* G_{\pi_{f^*\{A\}}} : Fam(\mathcal{C})_{\Gamma'} \rightarrow Fam(\mathcal{C})_{\Gamma'.f^*\{A\}}$ .

*Proof.* Let  $u : (\Gamma, \alpha) \rightarrow (\Gamma, \beta)$  be a morphism between two objects in  $Fam(\mathcal{C})_{\Gamma}$ . Then  $q_{A,f}^* G_{\pi_{f^*\{A\}}}(u)$  is a morphism between:

$$\begin{aligned} & \left( \{(\gamma', t) \mid \gamma' \in \Gamma', t : 1 \rightarrow A_{f(\gamma')}\}, \lambda(\gamma', t). \prod_{\gamma \in f(\text{fst}(\gamma', t))} \alpha(\gamma) \right) \rightarrow \\ & \left( \{(\gamma', t) \mid \gamma' \in \Gamma, t : 1 \rightarrow A_{f(\gamma')}\}, \lambda(\gamma', t). \prod_{\gamma \in f(\text{fst}(\gamma', t))} \beta(\gamma) \right) \end{aligned}$$

induced by the UMP of the product from the family of morphisms:  $u(\gamma) : \alpha(\gamma) \rightarrow \beta(\gamma)$ , while  $G_{\pi_A^*} f^*(u)$  is the morphism:

$$\begin{aligned} & \left( \{(\gamma', t) \mid \gamma' \in \Gamma', t : 1 \rightarrow A_{f(\gamma')}\}, \lambda(\gamma', t). \prod_{\gamma \in \text{fst}(f(\gamma'), t)} \alpha(\gamma) \right) \rightarrow \\ & \left( \{(\gamma', t) \mid \gamma' \in \Gamma, t : 1 \rightarrow A_{f(\gamma')}\}, \lambda(\gamma', t). \prod_{\gamma \in \text{fst}(f(\gamma'), t)} \beta(\gamma) \right) \end{aligned}$$

arising in the same way. But these are clearly isomorphic in a canonical way.  $\square$

To show that the families model supports  $\Pi$  and  $\Sigma$  type formers, then, it remains to check that there exists an isomorphism  $\Gamma.\Sigma_A B \cong \Gamma.A.B$ .

Expanding the left hand side, we get:

$$\{(\gamma, t) \mid \gamma \in \Gamma, t \in \prod_{((\gamma, a), b) \in \text{fst}^{-1}(\gamma, a)} ((\gamma, a), b)\}$$

while the right hand side is the set:

$$\{(\gamma, a, b) \mid \gamma \in \Gamma, a \in A_\gamma, b \in B_{A_\gamma}\}$$

which are isomorphic in a canonical way. The families model therefore supports the type formers  $\Pi$  and  $\Sigma$ . It is also clear that the families model supports  $\sqcap$ -types if  $\mathcal{V}$  has small products, and  $\sqcup$  if  $\mathcal{V}$  has small coproducts that distribute over  $\otimes$  (Frobenius reciprocity).

We can form extensional identity types in the families model, by interpreting propositional equality in the same way as our traditional set theoretic equality. That is, we define the family  $Id_A \in Fam(\mathbf{Sets})_{\Gamma.A.A\{\pi_A\}}$  by the function:

$$Id_A(\gamma, a \in A_\gamma, b \in A_\gamma) = \begin{cases} \{\star\}, & \text{if } a = b \\ \emptyset, & \text{otherwise.} \end{cases}$$

This gives rise to extensional identity types, which by lemma 5.17, forms support for identity types in the families model.

To deal with the operators  $M$  and  $L$ , we make use of the following lemma:

**Lemma 6.4.** An adjunction

$$\begin{array}{ccc} & F & \\ \mathcal{C} & \xleftarrow{\quad} & \mathcal{D} \\ & G & \end{array} \quad \perp$$

induces a fiber adjunction between the corresponding fibrations:

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \swarrow & \perp & \searrow \\
 \mathbf{Fam}(\mathcal{C}) & \xrightarrow{\mathbf{G}} & \mathbf{Fam}(\mathcal{D}) \\
 \searrow p & & \swarrow q \\
 & \mathbf{Sets} &
 \end{array}$$

*Proof.* Let  $\mathbf{G} : \mathbf{Fam}(\mathcal{C}) \rightarrow \mathbf{Fam}(\mathcal{D})$  and  $\mathbf{F} : \mathbf{Fam}(\mathcal{D}) \rightarrow \mathbf{Fam}(\mathcal{C})$  be the induced cartesian functors, defined pointwise in the obvious way. Define the vertical counit  $\epsilon : \mathbf{F}\mathbf{G} \Rightarrow 1_{\mathbf{Fam}(\mathcal{C})}$ , given at every component  $\{A\}_I \in \mathbf{Fam}(\mathcal{C})_I$  by the underlying counit,  $\epsilon_A = (1_I, \epsilon_{A_i})$ . For any morphism  $(u, \alpha) : \mathbf{F}(O, f) \rightarrow (O', g)$ , any morphism  $(v, \beta) : (O, f) \rightarrow \mathbf{G}(O', g)$  such that  $\epsilon_{(O', g)} \circ \mathbf{F}(v\beta) = (u, \alpha)$ , must satisfy  $v = u$ , since  $\mathbf{F}$  is constant on the function part of a morphism. But then each component of the family of morphisms,  $\beta$  is a morphism  $\beta_o : f(o) \rightarrow G(g(o'))$  fitting into the following diagram:

$$\begin{array}{ccc}
 F(f(o)) & \xrightarrow{F(\beta_o)} & FG(g(o')) \\
 & \searrow \alpha_o & \downarrow \epsilon_{g(o')} \\
 & & g(o')
 \end{array}$$

so by the universal property of the counit, each such  $\beta_o$  is uniquely defined.  $\square$

As a result, the families model supports the operators  $M$  and  $L$  whenever  $\mathcal{V}$  is a concrete category such that the free object generated by the singleton is the unit of the monoidal structure.

### 6.1.1 Universes in the families model

When it comes to universes, we need to be careful so as to not run into size issues. We want to construct universes which contains as many types as possible, without yielding any inconsistencies or collapsing the entire theory. As an example of such a collapse, consider the scenario where the category  $\mathcal{V}$  is small. Then we may define our linear universe  $L \in \mathbf{Fam}(\mathbf{Sets})_\Gamma$  as the constant family

$$(\Gamma, \lambda\gamma.Ob(\mathcal{V})).$$

Since any section of  $\pi(\mathcal{L}) : \Gamma.\mathcal{L} \rightarrow \Gamma$  consists of a selection of morphisms

$$f_\gamma : \mathbf{1} \rightarrow Ob(\mathcal{V}),$$

this defines an object  $(\Gamma, f)$  of  $\mathbf{Fam}(\mathcal{V})$  where  $f(\gamma) = f_\gamma(\star)$ . This universe will be closed under all purely linear type formers that are supported by  $\mathcal{V}$ , since these are constructed pointwise.

This may not be as desirable as it appears on first sight however, as at least in classical mathematics, a small  $\mathcal{V}$  supporting  $\square$  in the families model is necessarily a preorder, due to the following result:

**Theorem 6.5.** *Assuming the law of excluded middle, if a category  $\mathcal{V}$  has products indexed by the collection  $Arr(\mathcal{V})$  of arrows in  $\mathcal{V}$ , then  $\mathcal{V}$  is a preorder.*

*Proof.* Assume there are two distinct arrows  $f, g : A \rightarrow B$  between objects  $A, B \in \mathcal{V}$ . We can combine these arrows to get  $2^{|Arr(\mathcal{V})|}$  distinct arrows from  $a \rightarrow \prod_{[Arr(\mathcal{V})]} b$ , by the universal property of the product. But yields a contradiction, as this is obviously more arrows than exist in  $\mathcal{V}$ . By the law of the excluded middle, this double negation implies that there are no distinct arrows in  $\mathcal{V}$ .  $\square$

If we want  $\mathcal{V}$  to not be a preorder, it is clear that we need to be more careful in distinguishing between small and large types.

In order to deal with this distinction on the semantic side, we will need to introduce some new notions:

**Definition 6.6.** For an ordinal  $\alpha$ , the set  $\mathcal{V}_\alpha$ , is defined by transfinite induction as follows:

- $V_0 = \emptyset$
- $V_{\alpha+1} = \mathcal{P}(V_\alpha)$
- $V_\beta = \bigcup_{\alpha < \beta} (V_\alpha)$  ( $\beta$  is a limit).

The objects of **Set** consists of all of the sets such that they are elements of  $V_\alpha$ , for some  $\alpha$ . The collection of all such sets,  $V$  is not a set itself.

**Definition 6.7.** For any ordinal  $\alpha$ , the define the full subcategory **Set** $_\alpha$  of **Set**, whose objects are sets  $X$  such that  $X \in V_\alpha$ .

The idea is to select a large enough cardinal  $\kappa$ , such that **Set** $_\kappa$  can be thought of as a model of ZFC itself. This is the notion of a Grothendieck universe. First, recall the notion of an inaccessible cardinal:

**Definition 6.8.** A cardinal,  $\kappa$ , is said to be:

- **Uncountable**, if it is larger than the smallest infinite set.
- A **strong limit**, if for any  $\lambda < \kappa$ , we have  $2^\lambda < \kappa$ .
- **Regular**, if it is not the union of a family of sets of size  $< \kappa$  indexed by a set of size  $< \kappa$ .
- **Inaccessible**, if it is uncountable, a strong limit and regular.

It is important to keep in mind that the existence of inaccessible cardinals is independent of ZFC. But assuming their existence allows us to form a set theoretic universe which can model ZFC itself.

**Definition 6.9.** A **Grothendieck universe** is a set  $V_\kappa$  where  $\kappa$  is an inaccessible cardinal. With respect to such a universe, a set  $X$  is small if  $X \in V_\kappa$ , otherwise it is large.

Now calling **SETS** what we previously called **Set**, its full subcategory **SETS** $_\kappa$ , consisting of all  $\kappa$ -small sets is closed under all the usual operations of set theory, and has all limits and colimits for all  $\kappa$ -small diagrams. We can now enlarge the families model to the following comprehension category:

$$\begin{array}{ccc} Fam(\mathbf{SETS}) & \xrightarrow{\pi} & \mathbf{SETS}^{\rightarrow} \\ \downarrow \text{cod} & \swarrow \text{dom} & \\ \mathbf{SETS} & & \end{array}$$

and define the cartesian universe  $\mathcal{U} \in Fam(\mathbf{SETS})_\Gamma$  by the constant family:

$$\mathcal{U} = (\Gamma, \lambda\gamma.V_\kappa).$$

Any section  $t : \Gamma \rightarrow \Gamma.U$  defines a  $\Gamma$  indexed collection  $(\Gamma, t_\gamma)$  of sets in  $V_\kappa$ , which gives an interpretation of  $El(t)$ . Following closely the proof of theorem 6.2, paying attention to size, we get the following result:

**Corollary 6.10.** For any function  $u : S \rightarrow S'$  such that for each  $s \in S'$ , the subset  $u^{-1}(s)$  is small, the functor  $u^* : Fam(\mathbf{SETS})_{S'} \rightarrow Fam(\mathbf{SETS})_S$  has left and right adjoints,  $\Sigma$  and  $\Pi$ . Furthermore, for each family  $(S', f)$  in  $Fam(\mathbf{SETS})_S$ , each member of the family  $\Sigma(\Gamma, f) \in Fam(\mathbf{SETS})_S$  is small.

By this argument, we find that the enlarged families model supports cartesian universes that are closed under  $\Pi$  and  $\Sigma$ . Since the projections  $\pi_U : \Gamma.U \rightarrow \Gamma$  associated to universes are such that the sets  $\pi_U(\gamma)$  are small, for sections  $t : \Gamma \rightarrow \Gamma.U$  and  $s : \Gamma.El(t) \rightarrow \Gamma.El(t).U$ , define  $\hat{\Pi}_{El(t)}v$  as the section which associates each  $\gamma$  to the image of the member  $El(v)_\gamma$  under functor  $\Pi$ . The case for  $\Sigma$  is completely analogous.

Similarly, as long as  $Ob(\mathcal{V}) \in \mathbf{SETS}$ , we can define the linear universe as the family:

$$\mathcal{L} = (\Gamma, \lambda\gamma.Ob(\mathcal{V}))$$

Where a section  $t : \Gamma \rightarrow \Gamma.L$  defines a family  $El(t) = (\Gamma, t_\gamma)$  where  $t_\gamma \in \mathcal{V}$ .

By this construction, we recover the “small” families model as submodel of small types. Furthermore, by restricting the type formers  $M$ ,  $L \sqsubset$  and  $\sqcap$  to only be defined for small types, this linear universe is all-encompassing.

### 6.1.2 Concrete examples

To summarize, these are the conditions imposed in order to support all of the type formers described in section 4 using the families model:

- A metatheory in which we can construct a Grothendieck universe (in ZFC, at least one inaccessible cardinal).
- A symmetric monoidal closed category  $\mathcal{V}$ , with small products and coproducts, which distribute over the monoidal structure.
- An adjunction  $L \dashv M$  between  $\mathcal{V}$  and **SETS**, such that  $L\{*\}$  is isomorphic to the unit of the monoidal structure of  $\mathcal{V}$ .

Some concrete choices for  $\mathcal{V}$  that fulfill these conditions are:

- The category **AbGroups** of abelian groups with the monoidal structure given by the tensor product of abelian groups. Here  $L \dashv M$  arises from the free functor on abelian groups.
- More generally, for any commutative ring  $R$ , the category  $R\text{-}\mathbf{Mod}$  of modules over  $R$  with the free functor- forgetful functor- adjunction
- The category **CGTop** $_*$ , of pointed compactly generated topological spaces, with the smash product as monoidal structure. The functor  $M$  is here the forgetful functor which both forgets the base point and the topology, which has a left adjoint given by the discrete topology, and then taking the coproduct with the point to create a pointed space. The unit of **CGTop** $_*$  is the two point discrete set  $S^0$ , which is precisely the image of the point in the adjunction above.

### 6.1.3 Syntactic enriched categories

As an in depth example construction in the families model of linear dependent type theory, recall the notion of an enriched category in as defined in 3.12. Our goal is to construct a syntactic analogue of this construction in the families model, such that the interpretation of this is an enriched category. There are two ways of doing this. The first is a meta construction, in which we ask for the existence of certain types and judgemental equalities to hold, whereas the second, internal definition, is a type **Enr-Cat**, whose terms are interpreted as enriched categories. The type **Enr-Cat** allows us to formulate theorems about enriched categories directly in the syntax, but requires more involved type formers, such as universes, and the following type, with which we can reason (non-linearly) about the hom-sets of  $\mathcal{V}$ :

$\frac{\Gamma \vdash A \text{ linear} \quad \Gamma \vdash B \text{ linear}}{\Gamma \vdash [A, B] \text{ type}} \text{ hom-F}$	$\frac{\Gamma \vdash f : [A, B] \quad \Gamma; \Xi \vdash a : A}{\Gamma; \Xi \vdash f(a) : B} \text{ hom-E}$
$\frac{\Gamma; x : A \vdash t : B}{\Gamma \vdash [\lambda x. t] : [A, B]} \text{ hom-I}$	$\frac{\Gamma; x : A \vdash t : B \quad \Gamma; \Xi \vdash a : A}{\Gamma; \Xi \vdash [\lambda x. t](a) \equiv t[a/x] : B} \text{ hom-C}$

In the presence of linear function types ( $\multimap$ ) and the  $M$ -functor, this type can be just as well be constructed as  $(A \multimap B)_M$ . However, adding it as a primitive allows us to talk about the hom-sets of  $\mathcal{V}$  even when it is not closed. Instead, the semantics of  $[-, -]$  will be an object in  $\mathcal{T}$  which “represents” the morphisms of  $\mathcal{L}$ :

**Definition 6.11.** A model of linear dependent type theory supports  $[-, -]$ -types, if, for all objects  $A, B \in \mathcal{L}_\Gamma$ , there exists an object  $T[A, B] \in \mathcal{T}_\Gamma$  such that  $\mathcal{T}_\Gamma(X, T[A, B]) \cong \mathcal{L}_{\Gamma.X}(A, B)$ .

**Definition 6.12** (meta-theoretic enriched categories). A meta-theoretic  $\mathcal{V}$ -enriched category in a context  $\Gamma$  consists of the following data:

- A (cartesian) type  $\Gamma \vdash A$  type,
- for any  $x, y : A$ , a linear type  $\Gamma, x, y : A \vdash B_{x,y}$  linear,
- terms  $\Gamma, x, y, z : A; g : B_{y,z}, f : B_{x,y} \vdash M(g, f) : B_{x,z}$ ,
- $\Gamma, x : A; \cdot \vdash j_x : B_{x,x}$  and
- judgemental equalities  $\Gamma, x, y : A; f : B_{x,y} \vdash f \equiv M(j_y \otimes f)$  and  $\Gamma, x, y : A; f : B_{x,y} \vdash f \equiv M(f \otimes j_x)$ .

The interpretation of this in the families model are precisely  $\mathcal{V}$ -enriched categories. The underlying set of objects will be  $[[A]]$ , the interpretation of  $B$  is a function  $B : [[A]] \times [[A]] \rightarrow \mathcal{V}$ , which for each pair  $x, y \in A$  assigns an object of  $\mathcal{V}$ .

**Definition 6.13** (Internal enriched categories). The type **Enr-cat** is defined as

$$\text{Enr-Cat} := \Sigma_{A:\mathcal{U}} \Sigma_{B:\Pi_{x,y:A} \mathcal{L}} \Sigma_{M:\Pi_{x,y,z:A} [B_{y,z} \otimes B_{x,y}, B_{x,z}]} \Sigma_{j:\Pi_{x:A} [I, B_{x,x}]} [\lambda f.f] = [\lambda f.M_{x,x,y}(f \otimes j_x)] \times [\lambda f.f] = [\lambda f.M_{x,x,y}(j_y \otimes f)]$$

Since  $\text{Fam}(\mathbf{Set})$  is an extensional model, whenever the  $a =_A b$  is inhabited, we have  $[[a]] = [[b]]$ . Furthermore, since the equalities  $p, q$  and  $r$  are all identifying morphisms in the image of the faithful functor  $M$ , we have:

$$[[f \circ 1_x]] \equiv [[1_y \circ f]] \equiv [[f]]$$

and

$$[[h \circ (g \circ f)]] \equiv [[(h \circ g) \circ f]]$$

for all  $f : B_{x,y}, g : B_{y,z}$  and  $h : B_{z,w}$ , demonstrating that composition is unital and associative in the enriched category. For example, we may choose  $\mathcal{V}$  to be the category of groups equipped with the usual tensor product of groups. Here the  $L$  functor forms the free abelian group of a set, and the construction above will yield an Ab-enriched category.

## 6.2 Diagrams in monoidal categories

Expanding on the set indexed families example, for any category  $\mathcal{C}$ , there is a fibration  $\text{cod} : \mathbf{Diag}(\mathcal{C}) \rightarrow \mathbf{Cat}$ , with total category  $\mathbf{Diag}(\mathcal{C})$  begin the category of diagrams in  $\mathcal{C}$  whose objects are functors  $J : \mathcal{D} \rightarrow \mathcal{C}$ , and whose morphisms between  $J : \mathcal{D} \rightarrow \mathcal{V}$  and  $J' : \mathcal{C} \rightarrow \mathcal{V}$  consist of functors  $F : \mathcal{C} \rightarrow \mathcal{D}$  such that  $J \circ F = J'$ . In other words, the fibers of  $\mathbf{Diag}(\mathcal{C})$  are functor categories, which we write  $[\Gamma, \mathcal{C}]$ , for any small category  $\Gamma$ . Any functor  $F : \mathcal{A} \rightarrow \mathcal{B}$  in the base induces a canonical lift  $F^* : [\mathcal{B}, \mathcal{C}] \rightarrow [\mathcal{A}, \mathcal{C}]$  simply given by precomposition.

Again, when  $\mathcal{C}$  has a terminal object  $\top$  such that the collections  $\mathcal{C}(\top, A)$  are small for any  $A \in \mathcal{C}$ , then this forms a comprehension category,

$$\begin{array}{ccc} \mathbf{Diag}(\mathcal{C}) & \xrightarrow{\pi} & \mathbf{Cat} \\ \downarrow \text{dom} & \swarrow \text{cod} & \\ \mathbf{Cat} & & \end{array}$$

where the functor  $\pi$  is defined as follows. Given any diagram  $A : \Gamma \rightarrow \mathcal{C}$ , we let the category  $\Gamma.A$  be the **Grothendieck construction** for  $\Gamma$ , in other words, the category whose objects are pairs  $(\gamma, t_\gamma)$  where  $\gamma \in \Gamma$  and  $t_\gamma : 1 \rightarrow A(\gamma)$ . Morphisms  $(\gamma, t_\gamma) \rightarrow (\gamma', t_{\gamma'})$  consists of pairs  $(u, \alpha)$  where  $u : \gamma \rightarrow \gamma'$  is a functor and  $\alpha A(u) \circ t_\gamma \Rightarrow t_{\gamma'}$  is a natural transformation. The comprehension functor  $\pi : \mathbf{Diag}(\mathcal{C}) \rightarrow \mathcal{C} \text{-}\mathbf{Cat}$  sends the diagram  $A : \Gamma \rightarrow \mathcal{C}$  to obvious forgetful functor:

$$\begin{aligned} \pi_A : \Gamma.A &\rightarrow \Gamma \\ \pi(\gamma, a_\gamma) &= \gamma \end{aligned}$$

When  $\mathcal{C}$  is any symmetric monoidal category  $\mathcal{V}$ , there is an obvious symmetric monoidal structure on each fiber  $[\Gamma, \mathcal{V}]$ , given pointwise:

$$\begin{aligned} J \otimes J'(x) &= J(x) \otimes J'(x) : [\Gamma, \mathcal{V}] \\ J \otimes J'(f) &= J(f) \otimes J'(f) : J(x) \otimes J'(x) \rightarrow J(y) \otimes J'(y) \end{aligned}$$

Lifts are simply given by precomposition, and we confirm that for  $f : \Delta \rightarrow \Gamma$ , and  $A : \Gamma \rightarrow \mathcal{C}$ ,  $\pi(f^*)$  is the pullback:

$$\begin{array}{ccc} \Delta.A\{f^*\} & \xrightarrow{q} & \Gamma.A \\ \downarrow \pi_{A\{f^*\}} & & \downarrow \pi_A \\ \Delta & \xrightarrow{f} & \Gamma \end{array}$$

where  $q(\delta, a_{f(\delta)}) = (f(\delta), a_{f(\delta)})$ . Since reindexing functors are strictly monoidal, this yields a split monoidal fibration. Restricting the base to groupoids instead of categories, and setting  $\mathcal{C} = \mathbf{Gpd}$  we get a model of linear dependent type theory which expands the groupoid model by Hofmann and Streicher [7]:

$$\begin{array}{ccccc} \mathbf{Diag}(\mathcal{V}) & & \mathbf{Diag}(\mathbf{Gpd}) & \xrightarrow{\pi} & \mathbf{Gpd}^\rightarrow \\ & \searrow \text{dom} & \downarrow \text{dom} & & \swarrow \text{cod} \\ & & \mathbf{Gpd} & & \end{array}$$

Since  $\top$  is the groupoid  $\mathbf{1}$  consisting of a single object, we will equate the functor  $t_\gamma : \mathbf{1} \rightarrow A(\gamma)$  with an object  $a_\gamma$  of  $A(\gamma)$ , and the natural transformation  $\alpha : A(u) \circ t_\gamma \Rightarrow t_{\gamma'}$  with a morphism  $\alpha_\gamma : A(u)(a_\gamma) \rightarrow a_{\gamma'}$ .

As shown in [7], this model supports  $\Pi$  and  $\Sigma$ , and importantly provides an example of *Id*-types where there might be more terms of  $x =_A x$  than  $\text{refl}(x)$ , which sets the stage for the homotopy interpretation of dependent type theory. Here, the interpretation of identity type  $\text{Id}_A$  is the functor  $\text{Id}_A : \Gamma.A.A^+ \rightarrow \mathbf{Gpd}$  which sends an object  $(\gamma, a_\gamma, b_\gamma)$  to the discrete groupoid  $\delta \text{Hom}_{A(\gamma)}(\gamma)(a, b)$ , and a morphism  $(u, \alpha, \beta) : (\gamma, a_\gamma, b_\gamma) \rightarrow (\gamma', a_{\gamma'}, b_{\gamma'})$  to the functor  $\alpha^{-1} \circ A(u)(-) \circ \beta : \delta(\text{Hom}_A(a, b)) \rightarrow \delta(\text{Hom}_A(a', b'))$ , which sends  $f : a \rightarrow b$  to the composite  $\alpha^{-1} \circ A(u)(f) \circ \beta : a' \rightarrow A(u)a \rightarrow A(u)b \rightarrow b'$ .

We see that the extended context  $\Gamma.A.A^+.\text{Id}_A$  is equivalent to  $\Gamma.A^\rightarrow$ , and we define  $r_A : (\Gamma.A) \rightarrow (\Gamma.A^\rightarrow)$  to be the functor sending morphisms:

$$(u, \alpha) : (\gamma, a_\gamma) \rightarrow (\gamma', a_{\gamma'})$$

to squares:

$$\begin{array}{ccc} (\gamma, a_\gamma) & \xrightarrow{(u, \alpha)} & (\gamma', a_{\gamma'}) \\ \downarrow (1_\gamma, 1_{a_\gamma}) & & \downarrow (1_{\gamma'}, 1_{a_{\gamma'}}) \\ (\gamma, a_\gamma) & \xrightarrow{(u, \alpha)} & (\gamma', a_{\gamma'}) \end{array}$$

The following special case will become important:

**Lemma 6.14.** If a functor  $A : \Gamma \rightarrow \mathbf{Gpd}$  takes values in discrete groupoids only, then for any two sections  $M : \Gamma \rightarrow \Gamma.A$  and  $N : \Gamma \rightarrow \Gamma.A$ , if there exists a section  $P : \Gamma \rightarrow \Gamma.\text{Id}_A\{M\}\{N^+\}$  then  $M = N$ .

*Proof.* The groupoid  $\Gamma.\text{Id}_A\{M\}\{N^+\}$  has as objects

$$(\gamma, M_\gamma \in A(\gamma), N_\gamma \in A(\gamma)), f : M_\gamma \rightarrow N_\gamma$$

where  $M_\gamma \in A(\gamma)$  is determined by the section  $M : \Gamma \rightarrow \Gamma.A$ . If a section  $P : \Gamma \rightarrow \Gamma.\text{Id}_A\{M\}\{N^+\}$  exists, it must for each  $\gamma$ , pick out a morphism  $f : M_\gamma \rightarrow N_\gamma$ . But since  $A(\gamma)$  is a discrete groupoid,  $f$  can only be the identity morphism, and we must have  $M_\gamma = N_\gamma$ , for all  $\gamma \in \Gamma$ . Since every  $A(\gamma)$  is discrete, this implies that  $M = N$ .  $\square$

**Theorem 6.15.** For any indexed groupoid  $A$  in  $\Gamma$ , the construction  $\text{Id}_A$  described above forms support for *Id*-types in the diagrams model.

*Proof.* That  $\text{Id}_A$  satisfies condition (1) and (2) of definition 5.15 is proved in [7]. It remains to show that condition (3) is satisfied by this construction. Let  $C, \Xi \in \mathcal{L}_{\Gamma.A.A^+.\text{Id}_A}$ , and assume we have sections  $M, N : \Gamma \rightarrow \Gamma.A$  and  $P : \Gamma \rightarrow \Gamma.\text{Id}_A\{M\}\{N^+\}$ . We are given a natural transformation  $c : \Xi\{r_A\} \rightarrow C\{r_A\}$ , between between the two functors  $\Xi \circ r_A : \Gamma.A \rightarrow \Gamma.A.A^+.\text{Id}_A \rightarrow \mathcal{V}$  and  $C \circ r_A : \Gamma.A \rightarrow \Gamma.A.A^+.\text{Id}_A \rightarrow \mathcal{V}$  and need to display a natural transformation  $\hat{c}_{[M, N, P]}$  between:

$$\Xi \circ P^+ \circ N^+ \circ M : \Gamma \rightarrow \Gamma.A \rightarrow \Gamma.A.A^+ \rightarrow \Gamma.A.A^+.\text{Id} \rightarrow \mathcal{V}$$

to

$$C \circ P \circ N^+ \circ M : \Gamma \rightarrow \Gamma.A \rightarrow \Gamma.A.A^+ \rightarrow \Gamma.A.A^+.\text{Id}_A \rightarrow \mathcal{V}$$

such that  $\hat{c}_{[M,M,refl(M)]} = c\{M\}$ . The key point to observe is that there is always an isomorphism  $(\gamma, P_\gamma : M_\gamma \rightarrow N_\gamma) \cong (\gamma, 1_{M_\gamma} : M_\gamma \rightarrow M_\gamma)$  given by the commutative diagram:

$$\begin{array}{ccc} (\gamma, M_\gamma) & \xrightarrow{1_M} & (\gamma, M_\gamma) \\ \downarrow P & & \downarrow 1_M \\ (\gamma, N_\gamma) & \xrightarrow{P^{-1}} & (\gamma, M_\gamma) \end{array}$$

in the groupoid  $\Gamma.A^\rightarrow$ , giving rise to a natural isomorphism  $\phi : r_A \circ M \cong P^+ \circ N^+ \circ M$ . We define  $\hat{c}[M, N, P]$  as the composite:

$$\hat{c}[M, N, P] := \Xi_\phi \circ c\{M\} \circ C_{\phi^{-1}} : \Xi \circ P^+ \circ N^+ \circ M \rightarrow \Xi \circ r_A \circ M \rightarrow C \circ r_A \circ M \rightarrow C \circ P^+ \circ N^+ \circ M$$

. Notice that when  $M \equiv N$  and  $P = refl(M)$ ,  $\phi$  is the identity natural transformation.  $\square$

As in the families model, limits and colimits are constructed pointwise, and preserved by precomposition, so the model supports  $\&$ ,  $\top$ ,  $\oplus$ ,  $0$ , if  $\mathcal{V}$  has binary products, terminal object, binary coproducts and initial object respectively.

The situation for  $\multimap$  requires a bit of care. Under what conditions is the functor category  $[\mathcal{C}, \mathcal{V}]$  monoidal closed with respect to the pointwise tensor product? For all  $F \in [\mathcal{C}, \mathcal{V}]$ , we need to find a right adjoint to the functor  $- \otimes F : [\mathcal{C}, \mathcal{V}] \rightarrow [\mathcal{C}, \mathcal{V}]$ . In other words for all functors  $G, H$ , we need

For  $F, G, H : \mathcal{C} \rightarrow \mathcal{V}$  a natural transformation  $\eta : F \otimes G \rightarrow H$ , a natural transformation is for all  $g : z \rightarrow x$  and  $f : x \rightarrow y$  in  $\mathcal{C}$ , a diagram:

$$Fx \otimes Gx \xrightarrow{Fg \otimes Gf} Fz \otimes asd$$

Naively,  $F, G, H : \mathcal{C} \rightarrow \mathcal{V}$  a natural transformation  $\eta : F \otimes G \rightarrow H$  gives rise to a collection of maps  $\hat{\eta}_A : F(A) \rightarrow [G(A), H(A)]$ , but a priori these maps do not constitute a natural transformation  $F \rightarrow [G, H]$ . Instead, notice that a natural transformation  $\eta : F \rightarrow G$ , is for each morphism  $f : A \rightarrow B$  in  $\mathcal{C}$ , a pair of morphisms  $\eta_A$  and  $\eta_B$  such that:

$$\begin{array}{ccc} F(A) & \xrightarrow{Ff} & F(B) \\ \downarrow \eta_A & & \downarrow \eta_B \\ G(A) & \xrightarrow{Gf} & G(B) \end{array}$$

or equivalently, an “element” of  $[F(A), G(A)] \times [F(B), G(B)]$  such that the postcomposing the first component with  $Gf$  is the same as precomposing the second component with  $Ff$ :

$$[F(A), G(A)] \times [F(B), G(B)] \xrightarrow[\pi_2(Ff_*)]{\pi_1(Gf^*)} [F(A), G(B)]$$

So if  $\mathcal{V}$  has all limits, a natural candidate for the internal hom of the functor category becomes the equalizer:

$$[F, G](x) = Eq(\Pi_{x \in \mathcal{C}} [Fx, Gx]) \xrightarrow[Ff_*]{Gf^*} \Pi_{f : x \rightarrow y} [Fx, Gy]$$

also known as the end  $[F, G](x) = \int_{x \in \mathcal{C}} [Fx, Gx]$  of the functor  $[F-, G-] : \mathcal{C}^{op} \times \mathcal{C} \rightarrow \mathcal{V}$ .

**Theorem 6.16.** *If  $\mathcal{V}$  has internal homs and is complete,  $[\mathcal{C}, \mathcal{V}]$  has internal homs, defined as above.*

*Proof.* For any,  $F, G, H \in [\mathcal{C}, \mathcal{V}]$ , we need to display bijection

$$[\mathcal{C}, \mathcal{V}](H \otimes F, G) \cong [\mathcal{C}, \mathcal{V}](H, \int_{x \in \mathcal{C}} [Fx, Gx])$$

natural in  $G$  and  $H$ . Since  $[F, G]$  is a constant functor, a map on the right hand side consists of, for every map  $f : x \rightarrow y \in \text{Mor}(\mathcal{C})$ , of commutative diagrams of the following form:

$$\begin{array}{ccc} Hx & \xrightarrow{Hf} & Hy \\ & \searrow \eta_x & \downarrow \eta_y \\ & & \int_{x \in \mathcal{C}} [Fx, Gx] \end{array}$$

which will determine two unique morphisms,  $\hat{\eta}_x : Hx \rightarrow \Pi_{x \in \mathcal{C}}[Fx, Gx]$  and  $\hat{\eta}_y : Hy \rightarrow \Pi_{x \in \mathcal{C}}[Fx, Gx]$ , such that the following diagram commutes:

$$\begin{array}{ccc}
 Hx & \xrightarrow{Hf} & Hy \\
 & \searrow \hat{\eta}_x & \downarrow \hat{\eta}_y \\
 & & \Pi_{x \in \mathcal{C}}[Fx, Gx] \xrightarrow[\pi_2(Ff_*)]{\pi_1(Gf^*)} \Pi_{f:x \rightarrow y}[Fx, Gy]
 \end{array}$$

projecting out yields a unique collection of morphisms  $\pi_x \hat{\eta}_x : Hx \rightarrow [Fx, Gx]$  such that the following diagram commutes:

$$\begin{array}{ccc}
 Hx & \xrightarrow{Hf} & Hy \\
 \downarrow \pi_x \hat{\eta}_x & & \downarrow \pi_y \hat{\eta}_y \\
 [Fx, Gx] & & [Fy, Gy] \\
 & \searrow [1_{Fx}, Gf] & \downarrow [Ff, 1_{Gy}] \\
 & & [Fx, Gy]
 \end{array}$$

which by the tensor-hom adjunction in  $\mathcal{V}$  corresponds precisely to a diagram:

$$\begin{array}{ccc}
 Hx \otimes Fx & \xrightarrow{Hf \otimes Ff} & Hy \otimes Fy \\
 \downarrow \tilde{\eta}_x \pi_x & & \downarrow \tilde{\eta}_y \pi_y \\
 Gx & \xrightarrow{Gf} & Gy
 \end{array}$$

, determining a unique natural transformation  $H \otimes F \rightarrow G$ . This yields a bijection of homsets natural in all variables.  $\square$

Given any functor  $p : \mathcal{D} \rightarrow \mathcal{C}$  in the base, we have:

$$p^*([G, F]) = \lambda x. \int_{p(x) \in \mathcal{C}} [G(p(x)), F(p(x))] = \int_{x \in \mathcal{D}} [G(p(x)), F(p(x))] = [p^*G, p^*F]$$

so we get that the diagrams model supports  $\multimap$  if  $\mathcal{V}$  is monoidal closed and complete.

**Definition 6.17.** For any functor  $p : \mathcal{A} \rightarrow \mathcal{B}$  in the base, a left or right adjoint to the induced functor  $p^* : [\mathcal{B}, \mathcal{V}] \rightarrow [\mathcal{A}, \mathcal{V}]$  is called a **left or right Kan extension** of  $p$ .

So, in order for the diagrams model to support  $\sqcap$ - and  $\sqcup$ -types, we need left and right Kan extensions of every functor between small groupoids.

In order to interpret  $M$  and  $L$  in this model, the same argument as in lemma 6.4 can be used to show that an adjunction between  $\mathcal{V}$  and **Gpd** induces a fiber adjunction between the respective diagram categories. Also, since the composition of two adjunctions is again an adjunction, we get that whenever the functor  $\mathcal{V}(I, -) : \mathcal{V} \rightarrow \mathbf{Set}$  has a left adjoint  $F$ , then there exists an adjunction between **Diag**( $\mathcal{V}$ ) and **Diag**(**Gpd**), arising out of:

$$\begin{array}{ccccc}
 \mathcal{V} & \xleftarrow{F} & \mathbf{Set} & \xleftarrow{\pi_0} & \mathbf{Gpd} \\
 & \searrow \mathcal{V}(I, -) & \perp & \searrow \delta & \\
 & & & & 
 \end{array}$$

where  $\pi_0$  is the functor sending a groupoid to its set of connected components.

**Theorem 6.18.** *There are models in which  $M$  is not faithful.*

*Proof.* Let  $\mathcal{V}$  to be **Gpd** so that  $L = \delta \pi_0$  and  $M = \delta \mathbf{Gpd}(1, -)$ . This induces a fiber adjunction  $L \dashv M$  where  $L(1) = 1$ , but  $M$  is not faithful.  $\square$

### 6.2.1 Universes in the diagrams model

As in the families model, we can instead of the category of all small groupoids, we can shift our perspective to the category **GPD**, of all groupoids, assuming one inaccessible cardinal. Among the objects of **GPD** we find the large groupoid  $\text{core}(\mathbf{Gpd})$  and  $\text{core}(\mathcal{V})$ . This allows us to define our cartesian and linear universes in any context  $\Gamma$  as the functors:

$$U : \Gamma \rightarrow \mathbf{GPD}$$

$$L : \Gamma \rightarrow \mathbf{GPD}$$

which are constant at  $\text{core}(\mathbf{Gpd})$  and  $\text{core}(\mathcal{V})$ , respectively. Any section  $s : \Gamma \rightarrow \Gamma.U$  will determine a functor  $\hat{s} : \Gamma \rightarrow \mathbf{Gpd}$ , which we can embed via the full subcategory embedding  $\mathbf{Gpd} \rightarrow \mathbf{GPD}$  to get an interpretation of  $El(s)$ . Similarly, we get from each section  $s : \Gamma \rightarrow \Gamma.L$ , a functor  $El(s) : \Gamma \rightarrow \mathcal{V}$ . Restricting the type formers  $\Pi$ ,  $\sqsubset$ ,  $M$  and  $L$  to small types only, this linear universe is all-encompassing.

It is easily seen that defining the linear universe via the core of  $\mathcal{V}$  gives rise to the following interesting property, hinting at the possibility of a linear univalence axiom:

**Corollary 6.19.** For a linear universe defined as above via  $\text{core}(\mathcal{V})$ , and two sections  $s, t : \Gamma \rightarrow \Gamma.L$ , an isomorphism  $\alpha : El(t) \cong El(s)$  gives rise to a section  $p : \Gamma \rightarrow \Gamma.Id_L\{s\}\{t\}$ .

### 6.3 Univalence in linear dependent types

A key feature of the groupoid model is that it provides a model of dependent type theory where there might be nontrivial terms of the identity type. A natural question to ask is whether this higher dimensional feature of type theory can be extended to the linear dependent setting.

In particular, we want to explore a model in which the following, linear analogue to the univalence axiom, would hold:

$$\frac{\begin{array}{c} \Gamma \vdash A : L \\ \Gamma \vdash B : L \\ \Gamma; \cdot \vdash f : El(A) \multimap El(B) \\ \Gamma; \cdot \vdash g : El(B) \multimap El(A) \\ \Gamma; \cdot \vdash h : El(B) \multimap El(A) \\ \Gamma \vdash p : (g \circ f)_M =_{(El(A) \multimap El(A))_M} (id_A)_M \\ \Gamma \vdash q : (f \circ h)_M =_{(El(B) \multimap El(B))_M} (id_B)_M \end{array}}{\Gamma \vdash ua(f)_{[g,h,p,q]} : A =_L B} \text{ L-ua-I}$$

To define the corresponding computation rule, we first define a transport function for linear types:

**Lemma 6.20.** Suppose the following judgements hold:

$$\begin{array}{c} \Gamma, x : C \vdash D \text{ linear} \\ \Gamma \vdash a : C \\ \Gamma \vdash b : C \\ \Gamma \vdash p : a =_C b \end{array}$$

Then there is a linear function  $\Gamma; \cdot \vdash p^* : D[a/x] \multimap D[b/x]$ , which we call the **transport along p**

*Proof.*

$$\frac{\begin{array}{c} \Gamma, x, y : C \vdash D[x/x] \multimap D[y/x] \text{ linear} \\ \Gamma, z : C; \cdot \vdash \lambda u. u : D[z/x] \multimap D[z/x] \\ \Gamma \vdash a : C \\ \Gamma \vdash b : C \\ \Gamma \vdash p : a =_C b \end{array}}{\Gamma; \cdot \vdash R_{[x,y,p]}^{Id}(\lambda u. u, a, b, p) : D[a/x] \multimap D[b/x]}$$

□

Taking  $C \equiv L$ , and  $D \equiv El(x)$  for any  $x : L$  in the procedure above yields, from judgements:

$$\begin{array}{c} \Gamma \vdash A : L \\ \Gamma \vdash B : L \\ \Gamma \vdash p : A =_L B \end{array}$$

the function  $\Gamma; \cdot \vdash R_{[x,y,p]}^{Id}(\lambda u. u, A, B, p) : El(C) \multimap El(D)$ . It can easily be shown that this function gives rise to a linear equivalence between  $El(C)$  and  $El(D)$ . The two computation rules for the linear univalence axiom states that the procedure of generating an equivalence from an identity is itself an equivalence. In other words, given a linear function  $f : El(A) \multimap El(B)$  which gives rise to a linear equivalence of  $El(A)$  and  $El(B)$ , turning the equivalence  $f$  into an identity and then back into an equivalence should return  $f$  again:

$$\frac{\Gamma \vdash R_{[x,y,p]}^{Id}(\lambda u. u, A, B, ua(f)_{g,h,p,q}) : El(A) \multimap El(B)}{\Gamma \vdash R_{[x,y,p]}^{Id}(\lambda u. u, A, B, ua(f)_{g,h,p,q}) \equiv f : El(A) \multimap El(B)} \text{ L-ua-C}_1$$

and in the other direction, given an identity  $p : A =_L B$ , turning it to an equivalence and then back into an identity should return  $p$ :

$$\frac{\Gamma \vdash ua(f)_{[g,h,p,q]}(R_{[x,y,p]}^{Id}(\lambda u.u, A, B, p))_{[-,-,-,-]} : A =_L B}{\Gamma \vdash ua(f)_{[g,h,p,q]}(R_{[x,y,p]}^{Id}(\lambda u.u, A, B, p))_{[-,-,-,-]} \equiv p : A =_L B} \text{ L-ua-C}_2$$

### 6.3.1 Semantic justification

The semantic interpretation of the procedure of turning an identity to an equivalence above is the following:

**Lemma 6.21.** The syntactic composition operation for linear types,  $\cdot \circ \cdot$ , defined in 4.1, corresponds to the semantic operation of composition. More explicitly, given two terms  $\Gamma; \cdot \vdash f : A \multimap B$ , and  $\Gamma; \cdot \vdash g : B \multimap C$ , their interpretations  $[[f]] : I \rightarrow [A, B]$  and  $[[g]] : I \rightarrow [B, C]$  give rise to unique morphisms  $\hat{[[f]]} : A \rightarrow B$  and  $\hat{[[g]]} : B \rightarrow C$  via the tensor-hom adjunction. The interpretation of  $\Gamma; g \circ f : A \multimap C$  is a morphism  $[[f \circ g]] : I \rightarrow [A, C]$ , giving rise to  $\hat{[[f \circ g]]} : A \rightarrow C$ . The composite  $[[\hat{g}]] \circ [[\hat{f}]]$  and  $\hat{[[f \circ g]]}$  coincide.

*Proof.* Naturality like crazy.  $\square$

**Lemma 6.22.** Given two sections  $A, B : \Gamma \rightarrow \Gamma.L$ , and a section  $p : \Gamma \rightarrow \Gamma.Id_L\{A\}\{B^+\}$ , there is a natural isomorphism  $IdToEquiv(p) : El(A) \cong El(B)$  in  $[\Gamma, \mathcal{V}]$ .

*Proof.* The section  $p : \Gamma \rightarrow \Gamma.Id_L\{A\}\{B^+\}$  implies that...  $\square$

**Theorem 6.23.** When  $M$  factors through **Sets**, the linear univalence axiom holds in the diagrams model. That is, given the following data:

- sections:  $A, B : \Gamma \rightarrow \Gamma.L$
- morphisms:  $f : I \rightarrow [El(A), El(B)]$  and  $g, h : I \rightarrow El(B)$  in  $[\Gamma, \mathcal{V}]$ ,
- and sections:  $p : \Gamma \rightarrow \Gamma.Id_{(M[El(A), El(A)])}\{M(g \circ f)\}\{M(id_A)\}$  and  $q : \Gamma \rightarrow \Gamma.Id_{(M[El(B), El(B)])}\{M(f \circ h)\}\{M(id_B)\}$

Then there is a section  $ua(f)_{g,h,p,q} : \Gamma \rightarrow \Gamma.Id_L\{A\}\{B\}$  such that  $IdToEquiv(ua(f)) = f$  and  $ua(IdToEquiv(p)) = p$ .

*Proof.* Since  $M$  factors through sets, the interpretation of any type in its image  $M(C) : \Gamma \rightarrow \mathbf{Gpd}$  is a functor with values in discrete groupoids, so by lemma 6.14, the existence of a section  $p : \Gamma \rightarrow \Gamma.Id_{M[El(A), El(A)]}\{(g \circ f)_M\}\{(id_{El(A)})_M\}$  implies that the sections  $(g \circ f)_M : 1 \rightarrow M[A, A]$  and  $(id_{El(A)})_M : 1 \rightarrow M[A, A]$  coincide, which by the adjunction  $L \dashv M$  implies that  $[[g \circ f]] = id_{El(A)}$ . By lemma 6.21, and from the fact that the term  $id_{El(A)}$  corresponds to the identity morphism  $1_{El(A)} : El(A) \rightarrow El(A)$  via the tensor hom adjunction, this yields an isomorphism  $f : El(A) \rightarrow El(B)$  in **Diag**  $V_\Gamma$ , with  $g = h$  as inverse. Selecting this isomorphism in  $core(\mathcal{V})$  gives rise to a section  $P : \Gamma \rightarrow \Gamma.Id_L\{A\}\{B\}$ .  $\square$

So the linear univalence axiom holds in the diagrams model as long as  $M$  factors through sets. But this is not very satisfying from the perspective of homotopy type theory, since we simply showed this by collapsing all of our linear types to sets. Instead, we want to imagine a model where our linear types have an inherently higher dimensional structure. The first step to such a model is to let the objects of  $\mathcal{V}$  to be categories, and  $M$  be the functor taking a category to its core, i.e. its maximal sub-groupoid. If we want  $\mathcal{V}$  to have a non-cartesian monoidal structure the candidate choices **Cat** and **Gpd** won't do. As briefly outlined in 3.15 and carefully described in [15], there is a symmetric monoidal structure on **SMCat**, the category of small symmetric monoidal categories, symmetric monoidal functors and monoidal natural transformations.<sup>2</sup>

**Definition 6.24.** Let the **higher dimensional model of linear dependent type theory** be given by the diagrams model where  $\mathcal{V}$  is the 2-category of small symmetric monoidal categories, symmetric monoidal functors and monoidal natural transformations:

$$\begin{array}{ccccc} \text{Diag}(\mathbf{SMCat}) & & \text{Diag}(\mathbf{Gpd}) & \xrightarrow{\pi} & \mathbf{Gpd} \\ & \searrow \text{cod} & \downarrow \text{cod} & \swarrow \text{dom} & \\ & & \mathbf{Gpd} & & \end{array}$$

For two symmetric monoidal categories  $\mathcal{A}$  and  $\mathcal{B}$ , the category  $[\mathcal{A}, \mathcal{B}]$  consisting of monoidal functors and monoidal transformations between them carries a natural monoidal structure [15], and serves as the internal hom of  $\mathcal{A}$  and  $\mathcal{B}$ . Since **SMCat** is complete, with limits inherited from **Cat** equipped with a pointwise monoidal structure, we have support for  $\Pi$  and  $\&$ , and theorem 6.16 gives us that this model supports  $\multimap$  type formers.

<sup>3</sup>

<sup>2</sup>Technically, the structure on **SMCat** is not quite symmetric monoidal, as the associators, unitors and symmetry functors are only invertible up to higher homotopy. However, if one applies these homotopies whenever necessary, one does get a model of linear dependent type theory.

<sup>3</sup>Note, however, that we do not have all coproducts in **SMCat**. Therefore, we cannot support  $\oplus$  or  $\sqcup$ . An alternative to be explored is the category **Mult**, of multicategories, which is a symmetric monoidal closed, complete and bicomplete. [?]

**Lemma 6.25.** There is a functor  $F : \mathbf{Cat} \rightarrow \mathbf{SMCat}$  which constructs the free symmetric monoidal category of any groupoid, i.e. is a left adjoint to the forgetful functor  $U_{smcat} : \mathbf{SMCat} \rightarrow \mathbf{Cat}$ , forgetting the monoidal structure.

*Proof.* Construct the free symmetric monoidal category  $FC$  of a small category  $\mathcal{C}$  by letting the objects of  $FC$  be finite words  $(x_1, x_2, \dots, x_n)$  of the objects of  $\mathcal{C}$ . Morphisms between words are best thought of as string diagrams, where each string stems from a morphism in  $\mathcal{C}$ :

$$\begin{array}{ccc} y_1 & & y_2 \\ \curvearrowright & \xrightarrow{f} & \curvearrowleft \\ x_1 & & x_2 \end{array} \quad \begin{array}{c} y_3 \\ \uparrow h \\ x_3 \end{array}$$

The composition of such morphisms are just the composition of the corresponding string diagrams, composing the labels of strings along the way. The monoidal structure is simply given by concatenation of words, where the empty word corresponds to the unit. From this construction, it should be clear that given any symmetric monoidal groupoid  $\mathcal{D}$ , a functor between groupoids  $G : \mathcal{C} \rightarrow U_{smcat}\mathcal{D}$  induces a functor  $\hat{G}$  which maps words  $(x_1, x_2, \dots, x_n) \mapsto G(x_1) \otimes G(x_2) \otimes \dots \otimes G(x_n)$ , which forms an adjunction  $F \dashv U$ .  $\square$

Combining this adjunction with the familiar adjunction:

$$\begin{array}{ccc} & U_{gpd} & \\ \text{Cat} & \xleftarrow{\quad} & \mathbf{Gpd} \\ & \text{core} & \end{array} \quad \perp$$

where  $U_{gpd}$  is the forgetful functor and  $\text{core}$  is the functor sending a category to its underlying maximal sub-groupoid, we get an adjunction:

$$\begin{array}{ccc} & F \circ U_{gpd} & \\ \mathbf{SMCat} & \xleftarrow{\quad} & \mathbf{Gpd} \\ & \text{core} \circ U_{smcat} & \end{array} \quad \perp$$

This adjunction lifts by lemma 6.4 to a fiber adjunction:

$$\begin{array}{ccc} & L & \\ \text{Diag}(\mathbf{SMCat}) & \xleftarrow{\quad} & \text{Diag}(\mathbf{Gpd}) \\ & M & \\ & \text{cod} & \\ & \mathbf{Gpd} & \end{array} \quad \begin{array}{c} \perp \\ \text{cod} \end{array}$$

Furthermore, it is clear from the definition of  $F$  and the unit  $I$  of  $\mathbf{SMCat}$ , defined at ?? that the image of  $\mathbf{1}$  under  $F$  is precisely  $I$ , so the higher dimensional model supports  $M$  and  $L$  by the fiber adjunction  $F \dashv U$ .

The linear universe  $L$ , we take to be the groupoid consisting of all *discrete* symmetric monoidal categories, and isomorphisms between them. This is equivalently the core of  $\mathbf{CMon}$ , the category of small commutative monoids (in  $\mathbf{Set}$ ).  $\mathbf{CMon}$  is a full subcategory of  $\mathbf{SMCat}$ , which allows us to let  $El$  be the function sending an object of  $L$  to an object of  $\mathbf{SMCat}$ .

More explicitly, over any groupoid  $\Gamma$ , let  $\mathcal{L}$  be the functor  $L : \Gamma \rightarrow \mathbf{Gpd}$ , which is constant at  $\text{core}(\mathbf{CMon})$ . A section  $t : \Gamma \rightarrow \Gamma.L$  of its corresponding projection, selects for each  $\gamma$ , an object  $a_\gamma \in \text{core}(\mathbf{CMon})$  and for each morphism  $\alpha : \gamma \rightarrow \gamma'$ , an isomorphism  $a_\gamma \rightarrow a_{\gamma'}$ . This defines a functor  $\hat{t} : \Gamma \rightarrow \text{core}(\mathbf{CMon})$ , which we embed into  $\mathbf{SMCat}$  to get our interpretation of  $El(t) : \Gamma \rightarrow \mathbf{SMCat}$ .

### 6.3.2 Univalent linear type theory (syntactic)

Equipped with the new linear univalence axiom, we are able to prove equalities between types that are easily shown to be isomorphic.

**Theorem 6.26.** Assuming  $L\text{-ua}$ , for all linear types  $A, B, C$ , cartesian  $D$  in  $\Gamma$ , and cartesian  $E$  in  $\Gamma.D$ , the following types are inhabited:

1.  $\Gamma \vdash A \multimap B \multimap C =_{\mathcal{L}} A \otimes B \multimap C$
2.  $\Gamma \vdash (\Sigma_{x:D} E)_L =_{\mathcal{L}} \Sigma_{x:D} E_L$
3.  $(A \& B)_{LM} =_{\mathcal{L}} A_{LM} \otimes B_{LM}$

*Proof.* 1. We construct maps  $h : (A \multimap B \multimap C) \multimap (A \otimes B) \multimap C$

$$\begin{array}{c}
\text{--}\circ\text{-E} \frac{\Gamma; f : A \multimap B \multimap C \vdash f : A \multimap B \multimap C \quad \Gamma; y : A \vdash y : A}{\text{--}\circ\text{-E} \frac{\Gamma; f : A \multimap B \multimap C, y : A, z : B \vdash f(y) : B \multimap C \quad \Gamma; z : B \vdash z : B}{\Gamma; f : A \multimap B \multimap C, y : A, z : B \vdash f(y)(z) : C} \quad \Gamma; x : A \otimes B \vdash x : A \otimes B} \otimes\text{-E} \\
\frac{\Gamma; f : A \multimap B \multimap C, x : A \otimes B \vdash \text{let } x \text{ be } (y, z) \text{ in } f(y)(z) : C}{\Gamma; f : A \multimap B \multimap C \vdash \lambda x. \text{let } x \text{ be } (y, z) \text{ in } f(y)(z) : A \otimes B \multimap C} \text{--}\circ\text{-I} \\
\frac{\Gamma; \cdot \vdash \lambda f. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } f(a)(b) : (A \multimap B \multimap C) \multimap (A \otimes B \multimap C)}{\Gamma; \cdot \vdash \lambda f. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } f(a)(b) : (A \multimap B \multimap C) \multimap (A \otimes B \multimap C)} \text{--}\circ\text{-I}
\end{array}$$

and  $h^{-1} : (A \otimes B \multimap C) \multimap (A \multimap B \multimap C)$ :

$$\begin{array}{c}
\frac{\Gamma; \beta : B \vdash \beta : B \quad \Gamma; \alpha : A \vdash \alpha : A}{\Gamma; \alpha : A, \beta : B \vdash \alpha \otimes \beta : A \otimes B} \quad \Gamma; g : A \otimes B \multimap C \vdash g : A \otimes B \multimap C \\
\frac{\Gamma; g : A \otimes B \multimap C, \alpha : A, \beta : B \vdash g(\alpha \otimes \beta) : C}{\Gamma; g : A \otimes B \multimap C, \alpha : A \vdash g(\alpha \otimes \beta) : B \multimap C} \\
\frac{\Gamma; g : A \otimes B \multimap C \vdash \lambda \alpha. \lambda \beta. g(\alpha \otimes \beta) : A \multimap B \multimap C}{\Gamma; \cdot \vdash \lambda g. \lambda \alpha. \lambda \beta. g(\alpha \otimes \beta) : (A \otimes B \multimap C) \multimap (A \multimap B \multimap C)} \text{--}\circ\text{-I}
\end{array}$$

and show that they are mutually inverse.  $(h \circ h^{-1}) : (A \otimes B \multimap C) \multimap (A \otimes B \multimap C)$  reduces to:

$$\begin{aligned}
(h \circ h^{-1}) &\equiv \lambda \gamma. (\lambda f. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } f(a)(b)) (\lambda g. \lambda \alpha. \lambda \beta. g(\alpha \otimes \beta)) \gamma \equiv \\
&\lambda \gamma. (\lambda f. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } f(a)(b)) (\lambda \alpha. \lambda \beta. \gamma(\alpha \otimes \beta)) \equiv \\
&\lambda \gamma. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } (\lambda \alpha. \lambda \beta. \gamma(\alpha \otimes \beta))(a)(b) \equiv \\
&\lambda \gamma. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } \gamma(a \otimes b) \equiv \\
&\lambda \gamma. \text{let } (a \otimes b) \text{ be } (a, b) \text{ in } \gamma(a \otimes b) \equiv \\
&\text{id}_{(A \otimes B \multimap C) \multimap (A \otimes B \multimap C)}
\end{aligned}$$

and  $(h^{-1} \circ h) : (A \multimap B \multimap C) \multimap (A \multimap B \multimap C)$  reduces to:

$$\begin{aligned}
(h^{-1} \circ h) &\equiv \lambda \gamma. (\lambda g. \lambda \alpha. \lambda \beta. g(\alpha \otimes \beta)) (\lambda f. \lambda x. \text{let } x \text{ be } (a, b) \text{ in } f(a)(b)) \gamma \equiv \\
&\lambda \gamma. (\lambda g. \lambda \alpha. \lambda \beta. g(\alpha \otimes \beta)) (\lambda x. \text{let } x \text{ be } (a, b) \text{ in } \gamma(a)(b)) \equiv \\
&\lambda \gamma. \lambda \alpha. \lambda \beta. (\lambda x. \text{let } x \text{ be } (a, b) \text{ in } \gamma(a)(b))(\alpha \otimes \beta) \equiv \\
&\lambda \gamma. \lambda \alpha. \lambda \beta. \text{let } (\alpha \otimes \beta) \text{ be } (a, b) \text{ in } \gamma(a)(b) \equiv \\
&\lambda \gamma. \lambda \alpha. \lambda \beta. \gamma(\alpha)(\beta) \equiv \\
&\text{id}_{(A \multimap B \multimap C) \multimap (A \multimap B \multimap C)}
\end{aligned}$$

so we inhabit both  $(h \circ h^{-1})_M =_{(A \otimes B \multimap C) \multimap (A \otimes B \multimap C)} \text{id}_M$  and  $(h^{-1} \circ h)_M =_{(A \otimes B \multimap C) \multimap (A \otimes B \multimap C)} \text{id}_M$  with **refl**, and then apply the linear univalence axiom to get the desired equality.

- By Theorem 4.9, there is a linear equivalence  $(\Sigma_{x:D} E)_L \cong_{\square_{x:D}} E_L$ . The linear univalence axiom gives rise to an equality between these types.
- We construct a function  $f : (A \& B)_{LM} \multimap A_{LM} \otimes B_{LM}$  by:

$$f \equiv \lambda p. \text{let } p \text{ be } x \text{ in } \text{fst}(\sigma(x))_{LM} \otimes \text{snd}(\sigma(x))_{LM}$$

with inverse  $f^{-1} : A_{LM} \otimes B_{LM} \multimap (A \& B)_{LM}$ :

$$f^{-1} \equiv \lambda q. \text{let } q \text{ be } y, z \text{ in } \left( (\text{let } \alpha \text{ be } y \text{ in } \sigma(\alpha)), (\text{let } \beta \text{ be } z \text{ in } \sigma(\beta)) \right)_{LM}$$

which are easily seen to be mutually inverse. □
